Module Index

1.1 Modules

Here is a list of all modules:

Class_statevars	??
Competition_scheme_bioclim	??
Competition_scheme_existence	??
Competition_scheme_competition	??
Ctem_params_initpftpars	??
Ctem_statevars	??
Disturbance_scheme_disturb	??
Disturbance_scheme_burntobare	??
Hetresg	??
Hetresv	??
lo_driver_read_from_ctm	??
lo_driver_write_ctm_rs	??
lo_driver_create_outfiles	??
lo_driver_class_monthly_aw	??
lo_driver_class_annual_aw	??
lo_driver_ctem_daily_aw	??
lo_driver_ctem_monthly_aw	??
lo_driver_ctem_annual_aw	??
lo_driver_close_outfiles	??
Landuse_change_initialize_luc	??
Landuse_change_readin_luc	??
Landuse_change_luc	??
Landuse_change_adjust_luc_fracs	??
Landuse_change_adjust_fracs_comp	??
Moss_photosynthesis	??
Peat_soil_het_resp	??
Read_from_job_options	??
Parsecoords	??

Chapter 2

Data Type Index

2.1 Data Types List

Here are the data types with brief descriptions:

class_statevars::class_gather	??
class_statevars::class_moyr_output	
CLASS's monthly outputs	??
class_statevars::class_rotated	??
ctem_statevars::ctem_annual	
CTEM's average annual values (per PFT)	??
ctem_statevars::ctem_gridavg	
CTEM's grid average variables	??
ctem_statevars::ctem_gridavg_annual	
CTEM's grid average annual values	??
ctem_statevars::ctem_gridavg_monthly	
CTEM's grid average monthly values	??
ctem_statevars::ctem_monthly	
CTEM's variables monthly averaged (per pft)	??
ctem_statevars::ctem_switches	
Switches for running the model, read from the joboptions file	??
ctem_statevars::ctem_tile_level	
CTEM's variables per tile	??
ctem_statevars::ctem_tileavg_annual	
CTEM's variables per tile annual values	??
ctem_statevars::ctem_tileavg_monthly	
CTEM's variables per tile monthly values	??
datatransfermodule::datapackage	??
outputmanager::netcdfvar	??
outputmanager::outputdescriptor	
This data structure is used to set up the output netcdf files	??
outputmanager::simulationdomain	??
ctem_statevars::veg_gat	
CTEM's 'gat' vars	??
ctem_statevars::veg_rot	
CTEM's 'rot' vars	??
xmlparser::xml_parse	??
xmlparser::xml_report_details	??
xmlparser::xml_report_errors	??

Chapter 3

File Index

3.1 File List

Here is a list of all documented files with brief descriptions:

src/ allocate.f	Canadian Terrestrial Ecosystem Model (CTEM) Allocation Subroutine	??
src/ APREP.f	Purpose: Calculate various land surface parameters	??
src/ balcar.f	Canadian Terrestrial Ecosystem Model (CTEM) Carbon Balance Subroutine	??
src/ bio2str.f	Biomass To Structural Attributes Conversion Subroutine	??
src/ CANADD.f	Purpose: Calculate canopy interception of rainfall and snowfall, and determine rainfall/snowfall rates at ground surface as a result of throughfall and unloading	??
src/ CANALB.f	Purpose: Calculate vegetation albedos, transmissivities and stomatal resistances	??
src/ CANVAP.f	Purpose: Update liquid and frozen water stores on canopy and in soil in response to calculated sublimation, evaporation and transpiration rates	??
src/ CGROW.f	Purpose: Evaluate growth index used in calculating vegetation parameters for forests	??
src/ CHKWAT.f	Purpose: Check for closure of surface water budget, and for unphysical values of certain variables	??
src/ class_statevars.f90	This module contains the variable type structures:	??
src/ CLASSA.f	Purpose: Organize calculation of radiation-related and other surface parameters	??
src/ CLASSB.f	Purpose: Assign thermal and hydraulic properties to soil layers based on sand/clay content, or soil type. Also calculate permeable thickness of soil layers, and wet and dry surface albedo for mineral soils	??
src/ CLASSBD.f	Purpose: Assign values to parameters in CLASS common blocks. CLASS incorporates several kinds of parameters in its common blocks. Some are defined specifically for use in the CLASS code; some are also shared with the atmospheric model (if running in coupled mode)	??
src/ CLASSD.f	Purpose: Assign values to parameters in CLASS common blocks. CLASS incorporates several kinds of parameters in its common blocks. Some are defined specifically for use in the CLASS code; some are also shared with the atmospheric model (if running in coupled mode)	??

src/CLASSG.f	Purpose: Gather variables from two-dimensional arrays (latitude circle x mosaic tiles) onto long vectors for optimum processing efficiency on vector supercomputers	??
src/CLASSI.f	Purpose: Evaluate atmospheric variables and rainfall/snowfall rates over modelled area	??
src/CLASSIC.F90	Principle driver program to run CLASSIC in stand-alone mode using specified boundary conditions and atmospheric forcing. Depending upon the compiler options chosen, this program will either run in MPI mode for use on parallel computing environments or in serial mode for use in running at single sites	??
src/CLASSS.f	Purpose: Scatter variables from long, gathered vectors back onto original two-dimensional arrays (latitude circle x mosaic tiles)	??
src/CLASST.f	Purpose: Call subroutines to perform surface energy budget calculations	??
src/CLASSW.f	Purpose: Call subroutines to perform surface water budget calculations	??
src/CLASSZ.f	Purpose: Check for energy and water balance closure over modelled area	??
src/competition_map.f	Canadian Terrestrial Ecosystem Model (CTEM) Mapping For Competition Subroutine	??
src/competition_mod.f90	Central module for all competition scheme-related operations	??
src/competition_unmap.f	Canadian Terrestrial Ecosystem Model (CTEM) Unmapping For Competition	??
src/ctem.f90	Principle driver for CTEM	??
src/ctem_params.f90	This module holds CTEM globally accessible parameters. These parameters are used in all CTEM subroutines via use statements pointing to this module EXCEPT PHTSYN3.f which has the information passed in via arguments. This is a legacy thing	??
src/ctem_statevars.f90	This module contains the variable type structures:	??
src/ctemg1.f	Canadian Terrestrial Ecosystem Model (CTEM)	??
src/ctemg2.f	Canadian Terrestrial Ecosystem Model (CTEM)	??
src/ctems1.f	Canadian Terrestrial Ecosystem Model (CTEM)	??
src/ctems2.f	Canadian Terrestrial Ecosystem Model (CTEM)	??
src/CWALC.f	Purpose: Check for freezing or thawing of liquid or frozen water on the vegetation canopy, and adjust canopy temperature and intercepted water stores accordingly	??
src/disturb.f90	Update fractional coverages of pfts to take into account the area burnt by fire. Adjust all pools with new densities in their new areas and increase bare fraction	??
src/DRCOEF.f	Purpose: CALCULATES DRAG COEFFICIENTS AND RELATED VARIABLES FOR CLASS	??
src/GATPREP.f	Purpose: Assign values to pointer vectors relating the location of elements on the "gathered" variable vectors to elements on the original two-dimensional arrays (latitude circle x mosaic tiles) for land grid cells	??
src/GRALB.f	Purpose: Calculate visible and near-IR ground albedos	??
src/GRDRAN.f	Purpose: Quantify movement of liquid water between soil layers under non-infiltrating conditions, in response to gravity and tension forces	??

src/GRINFL.f	Purpose: Quantify movement of liquid water between soil layers under conditions of infiltration	??
src/hetres_mod.f90	Heterotrophic Respiration Subroutine For Vegetated Fraction	??
src/ICEBAL.f	Purpose: Perform temperature stepping and surface runoff calculations over ice sheets	??
src/io_driver.f90	Central module that handles all CTEM reading and writing of external files	??
src/landuse_change_mod.f90	Central module for all land use change operations	??
src/main.f90	Main model driver for CLASSIC in stand-alone mode using specified boundary conditions and atmospheric forcing. This driver program initializes the run, reads in CLASS input files, manages the run and the coupling between CLASS and CTEM, writes the CLASS sub-monthly outputs, and closes the run	??
src/mainres.f	Canadian Terrestrial Ecosystem Model (CTEM) Maintenance Respiration Subroutine	??
src/mortality.f	Canadian Terrestrial Ecosystem Model (CTEM) Mortality Subroutine	??
src/mvidx.f		??
src/ORDLEG.f	THIS ROUTINE IS A SUBSET OF BELOUSOV'S ALGORITHM USED TO CALCULATE ORDINARY LEGENDRE POLYNOMIALS	??
src/peatlands_mod.f90	Central module for all peatland-related operations	??
src/phenolgy.f	Canadian Terrestrial Ecosystem Model (CTEM) Phenology, Leaf Turnover & Mortality Subroutine	??
src/phenolgy.f90	Canadian Terrestrial Ecosystem Model (CTEM) Phenology, Leaf Turnover & Mortality Subroutine	??
src/PHTSYN3.f	CANADIAN TERRESTRIAL ECOSYSTEM MODEL (CTEM) PHOTOSYNTHESIS SUBROUTINE	??
src/read_from_job_options.f90	Module for parsing command line arguments to program and reading joboptions files	??
src/SCREENRH.f	CALCULATES SCREEN RELATIVE HUMIDITY BASED ON INPUT SCREEN TEMPERATURE, SCREEN SPECIFIC HUMIDITY AND SURFACE PRESSURE. THE FORMULAE USED HERE ARE CONSISTENT WITH THAT USED ELSEWHERE IN THE GCM PHYSICS	??
src/SLDIAG.f	CALCULATES NEAR SURFACE OUTPUT VARIABLES	??
src/SNINFL.f	Purpose: Address infiltration of rain and meltwater into snow pack, and snow ripening	??
src/SNOADD.f	Purpose: Add snow incident on the ground surface to the snow pack	??
src/SNOALBA.f	Purpose: Diagnose snowpack visible and near-IR albedos given the all-wave albedo at the current time step. Calculate snowpack transmissivity for shortwave radiation	??
src/SNOVAP.f	Purpose: Sublimation calculations for the snow pack on the ground	??
src/soil_ch4uptake.f90	Canadian Terrestrial Ecosystem Model (CTEM) Soil Methane Oxidation Subroutine	??
src/STORVAR.f		??
src/SUBCAN.f	Purpose: Assess water flux elements at the ground surface under the vegetation canopy	??
src/TFREEZ.f	Purpose: Address freezing of water ponded on ground surface	??

src/ TMCALC.f	Purpose: Calculate overland flow; step ahead pond and soil layer temperatures, and check for freezing of the pond and freezing or thawing of liquid or frozen water in the soil layers. Adjust pond temperature, soil layer temperatures and water stores accordingly	??
src/ TMELT.f	Purpose: Address melting of the snow pack	??
src/ TNPOST.f	Purpose: Soil heat flux calculations and cleanup after surface energy budget calculations . . .	??
src/ TNPREP.f	Purpose: Calculate coefficients for solution of heat conduction into soil	??
src/ TPREP.f	Purpose: Initialize subarea variables and calculate various parameters for surface energy budget calculations	??
src/ TSOLVC.f	Purpose: Solution of surface energy balance for vegetated subareas	??
src/ TSOLVE.f	Purpose: Solution of surface energy balance for non-vegetated subareas	??
src/ TSPOST.f	Purpose: Snow temperature calculations and cleanup after surface energy budget calculations	??
src/ TSPREP.f	Calculate coefficients for solution of snow pack heat conduction	??
src/ turnover.f	Canadian Terrestrial Ecosystem Model (CTEM) Stem And Root Turnover Subroutine	??
src/ TWCALC.f	Check for freezing or thawing of liquid or frozen water in the soil layers, and adjust layer temperatures and water stores accordingly	??
src/ WEND.f	Purpose: Recalculate liquid water content of soil layers after infiltration, and evaluate baseflow	??
src/ wetland_methane.f90	Canadian Terrestrial Ecosystem Model (CTEM) Wetland and wetland methane subroutine . . .	??
src/ WFILL.f	Purpose: Evaluate infiltration of water into soil under unsaturated conditions	??
src/ WFLOW.f	Evaluates infiltration of water into soil under saturated conditions	??
src/ WPREP.f	Purpose: Initialize subarea variables for surface water budget calculations, and perform preliminary calculations for diagnostic variables	??
src/ XIT.f	Purpose: Print the name of the subroutine and an error code when an error condition is encountered	??

Chapter 4

Module Documentation

4.1 Class_statevars

4.2 Competition_scheme_bioclim

Canadian Terrestrial Ecosystem Model (CTEM) Bioclimatic Parameters Estimation Subroutine.

- subroutine, public `competition_scheme::bioclim` (iday, ta, precip, netrad, il1, il2, nilg, leapnow, tcurm, srpcuryr, dftcuryr, inibioclim, tmonth, anpcpcur, anpecur, gdd5cur, surmncur, defmncur, srplscur, defctcur, twarmm, tcoldm, gdd5, aridity, srplsmon, defctmon, anndefct, annsrpls, annpcp, dry_season_length)

4.2.1 Detailed Description

Canadian Terrestrial Ecosystem Model (CTEM) Bioclimatic Parameters Estimation Subroutine.

The mortality associated with bioclimatic criteria, $m_{bioclim}$, ensures that PFTs do not venture outside their bioclimatic envelopes. The bioclimatic criteria that determine PFT existence are listed in Table `tab:pftparams` for tree PFTs. Bioclimatic limits are not used for the C_3 and C_4 grass PFTs. The bioclimatic limits represent physiological limits to PFT survival that are either not captured in the model or processes that are not sufficiently described by empirical observations to allow their parametrization. Some examples of the latter include a plant's resistance to frost damage and xylem cavitation limits due to moisture stress. The bioclimatic criteria include the minimum coldest month air temperature (T_{min}^{cold}), the maximum coldest month air temperature (T_{max}^{cold}), the maximum warmest month air temperature (T_{max}^{warm}), the minimum number of annual growing degree days above $5^\circ C$ ($GDD5_{min}$), the minimum annual aridity index (ratio of potential evapotranspiration to precipitation; $arid_{min}$) and the minimum dry season length in a year ($dryseason_{min}$), where the dry season length represents the number of consecutive months with precipitation less than potential evaporation. The bioclimatic indices are updated on a 25 year timescale ($T = 25$) such that the slowly changing value of a bioclimatic index $X(t+1)$ for time $t+1$ is updated using its previous year's value $X(t)$ and its value $x(t)$ for the current year as

$$X(t+1) = X(t)e^{-1/T} + x(t)(1 - e^{-1/T}).$$

Equation (efold) implies that 63 % of a sudden change in the value of a bioclimatic index Δx is reflected in $X(t)$ in T years ($1 - e^{T(-1/T)} = 1 - e^{-1} = 0.63$), while 86 % of the change is reflected in $2T$ years ($1 - e^{2T(-1/T)} = 1 - e^{-2} = 0.86$).

4.2.2 Function/Subroutine Documentation

4.2.2.1 subroutine, public `competition_scheme::bioclim` (integer, intent(in) iday, real, dimension(nilg), intent(in) ta, real, dimension(nilg), intent(in) precip, real, dimension(nilg), intent(in) netrad, integer, intent(in) il1, integer, intent(in) il2, integer, intent(in) nilg, logical, intent(in) leapnow, real, dimension(nilg), intent(inout) tcurm, real, dimension(nilg), intent(inout) srpcuryr, real, dimension(nilg), intent(inout) dftcuryr, logical, intent(inout) inibioclim, real, dimension(12,nilg), intent(inout) tmonth, real, dimension(nilg), intent(inout) anpcpcur, real, dimension(nilg), intent(inout) anpecur, real, dimension(nilg), intent(inout) gdd5cur, real, dimension(nilg), intent(inout) surmncur, real, dimension(nilg), intent(inout) defmncur, real, dimension(nilg), intent(inout) srplscur, real, dimension(nilg), intent(inout) defctcur, real, dimension(nilg), intent(inout) twarmm, real, dimension(nilg), intent(inout) tcoldm, real, dimension(nilg), intent(inout) gdd5, real, dimension(nilg), intent(inout) aridity, real, dimension(nilg), intent(inout) srplsmon, real, dimension(nilg), intent(inout) defctmon, real, dimension(nilg), intent(inout) anndefct, real, dimension(nilg), intent(inout) annsrpls, real, dimension(nilg), intent(inout) annpcp, real, dimension(nilg), intent(inout) dry_season_length)

Parameters

in	iday
----	------

Find current month

Find if we are at end of month or not

Update monthly temperature for the current month, and other variables. at the end of the month we will have average of all daily temperatures for the current month.

If its the end of the month then store the monthly temperature and set tcurm equal to zero. also check if this month had water deficit or surplus

this loop doubles up the size of the "wet_dry_mon_index" matrix

If its the end of year, then find the temperature of the warmest and the coldest month

Update long term moving average of bioclimatic parameters in an e-folding sense

4.3 Competition_scheme_existence

Canadian Terrestrial Ecosystem Model (CTEM) PFT Existence Subroutine.

- subroutine, public [competition_scheme::existence](#) (iday, il1, il2, nilg, sort, nol2pfts, twarmm, tcoldm, gdd5, aridity, srplsmon, defctmon, anndefct, annsrpls, annpcp, pftexist, dry_season_length)

4.3.1 Detailed Description

Canadian Terrestrial Ecosystem Model (CTEM) PFT Existence Subroutine.

4.3.2 Function/Subroutine Documentation

4.3.2.1 subroutine, public `competition_scheme::existence` (integer, intent(in) *iday*, integer, intent(in) *il1*, integer, intent(in) *il2*, integer, intent(in) *nilg*, integer, dimension(icc), intent(in) *sort*, integer, dimension(ican), intent(in) *nol2pfts*, real, dimension(nilg), intent(in) *twarmm*, real, dimension(nilg), intent(in) *tcoldm*, real, dimension(nilg), intent(in) *gdd5*, real, dimension(nilg), intent(in) *aridity*, real, dimension(nilg), intent(in) *srplsmon*, real, dimension(nilg), intent(in) *defctmon*, real, dimension(nilg), intent(in) *anndefct*, real, dimension(nilg), intent(in) *annsrpls*, real, dimension(nilg), intent(in) *annpcp*, logical, dimension(nilg,icc), intent(out) *pftexist*, real, dimension(nilg), intent(in) *dry_season_length*)

Parameters

in	<i>iday</i>	
----	-------------	--

Constants and parameters are located in [ctem_params.f90](#)

go through all grid cells and based on bioclimatic parameters decide if a given pft should exist or not.

needleleaf evergreen

needleleaf deciduous

broadleaf evergreen

broadleaf deciduous cold (see note below pft 5 too)

broadleaf deciduous dry

We don't want both broadleaf species co-existing so if it has PFT 5 remove PFT 4.

c3 and c4 crops

c3 grass

```
if(tcoldm(i).le.tcoldmax(sort(j)))then
```

```
else pftexist(i,j)=.false. endif
```

c4 grass

```
if(tcoldm(i).ge.tcoldmin(sort(j)))then
```

```
else pftexist(i,j)=.false. endif
```

4.4 Competition_scheme_competition

Canadian Terrestrial Ecosystem Model (CTEM) PFT Competition Subroutine.

- subroutine, public [competition_scheme::competition](#) (iday, il1, il2, nilg, nol2pfts, nppveg, dofire, leapnow, pftexist, geremort, intrmort, gleafmas, bleafmas, stemmass, rootmass, litrmass, soilcmas, grclarea, lambda, burnveg, sort, pstemmass, pgleafmass, fcanmx, fcanmx, vgbiomas, gavglms, gavgscms, bmasveg, add2allo, colrate, mortrate)

4.4.1 Detailed Description

Canadian Terrestrial Ecosystem Model (CTEM) PFT Competition Subroutine.

4.4.2 Function/Subroutine Documentation

4.4.2.1 subroutine, public `competition_scheme::competition` (integer, intent(in) *iday*, integer, intent(in) *il1*, integer, intent(in) *il2*, integer, intent(in) *nilg*, integer, dimension(ican), intent(in) *nol2pfts*, real, dimension(nilg,icc), intent(inout) *nppveg*, logical, intent(in) *dofire*, logical, intent(in) *leapnow*, logical, dimension(nilg,icc), intent(in) *pftexist*, real, dimension(nilg,icc), intent(in) *geremort*, real, dimension(nilg,icc), intent(in) *intrmort*, real, dimension(nilg,icc), intent(inout) *gleafmas*, real, dimension(nilg,icc), intent(inout) *bleafmas*, real, dimension(nilg,icc), intent(inout) *stemmass*, real, dimension(nilg,icc), intent(inout) *rootmass*, real, dimension(nilg,iccp1), intent(inout) *litrmass*, real, dimension(nilg,iccp1), intent(inout) *soilcmas*, real, dimension(nilg), intent(in) *grclarea*, real, dimension(nilg,icc), intent(in) *lambda*, real, dimension(nilg,icc), intent(in) *burnveg*, integer, dimension(icc), intent(in) *sort*, real, dimension(nilg,icc), intent(in) *pstemmass*, real, dimension(nilg,icc), intent(in) *pgleafmass*, real, dimension(nilg,icc), intent(inout) *fcanmx*, real, dimension(nilg,ican), intent(inout) *fcanmx*, real, dimension(nilg), intent(inout) *vgbiomas*, real, dimension(nilg), intent(inout) *gavglms*, real, dimension(nilg), intent(inout) *gavgscms*, real, dimension(nilg,icc), intent(inout) *bmasveg*, real, dimension(nilg,icc), intent(out) *add2allo*, real, dimension(nilg,icc), intent(out) *colrate*, real, dimension(nilg,icc), intent(out) *mortrate*)

Parameters

in	<i>iday</i>
----	-------------

set competition parameters according to the model chosen

First, let's adjust the fractions if fire is turned on.

Since the biomass pools could have changed, update bmasveg.

Do our usual initialization

initial rank/superiority order for simulating competition. since crops are not in competition their rank doesn't matter and therefore we only have icc-2 ranks corresponding to the remaining pfts. the first icc-4 are tree pfts and the last two are the c3 and c4 grasses.

Estimate colonization and mortality rate for each pft, except for crops whose fractional coverage is prescribed.

colonization rate (1/day). the factor (deltat/963.62) converts npp from u-mol co2-c/m2.sec -> kg c/m2.day

mortality rate is the sum of growth related mortality, intrinsic mortality, and an additional mortality that kicks in when long term averaged bioclimatic conditions become unfavourable for a pft. this last term is based on the binary array pftexist.

—> from here on we assume that we only have icc-numcrops pfts <— since crops are not part of the competition.

based on npp for each pft find the competition ranks / superiority order for simulating competition. note that crops are not in competition, so the competition is between the remaining pfts. in addition pfts which shouldn't exist in the grid cell because of unfavourable values of long-term climatic conditions are considered inferior.

bubble sort according to colonization rates NOTE - this only works if no tree species are indexed at positions > numtreepfts, i.e. the trees must be a contiguous unit at the start of the indexes. JM Jun 2014

the rank of c3 and c4 grass is also determined on the basis of their npp but grasses are always assumed to be inferior to tree pfts

with the ranks of all pfts in all grid cells we can now simulate competition between them. for lotka-volterra eqns we need a minimum seeding fraction otherwise the pfts will not expand at all.

arrange colonization and mortality rates, and fractions, according to superiority ranks

update fractions and check if all fractions are +ve

with the minimum seeding fraction prescription, especially for lotka volterra eqns the total veg fraction may exceed 1. to prevent this we need to adjust fractional coverage of all non-crop pfts that do not have the minimum fraction.

check again that total veg frac doesn't exceed 1.

map delfrac to chngfrac so that we get change in fraction corresponding to the actual number of pfts

—> from here on we get back to our usual icc pfts <—

get bare fraction

check if a pft's fractional cover is increasing or decreasing

check if bare fraction increases or decreases

now that we know the change in fraction for every pft we use its npp for spatial expansion and litter generation. we also spread vegetation biomass uniformly over the new fractions, and generate additional litter from mortality if the fractions decrease.

three things can happen here

1. $\text{fraciord} = 0$, which means all npp that was used for expansion becomes litter, due to self/expansion thinning and mortality.
2. $\text{fraciord} = 1$, which means a part of or full npp is used for expansion but some litter may also be generated. the part of npp that is used for expansion needs to be allocated to leaves, stem, and root. rather than doing this here we will let the allocation part handle this. so allocation module will allocate not only the npp that is used for pure vertical expansion but also this npp. but we will do our part here and spread the vegetation biomass over the new increased fraction.
3. $\text{fraciord} = -1$, which means all of the npp is to be used for litter generation but in addition some more litter will be generated from mortality of the standing biomass.

All npp used for expansion becomes litter plus there is additional mortality of the standing biomass. the npp that becomes litter is now spread over the whole grid cell. all biomass from fraction that dies due to mortality is also distributed over the litter pool of whole grid cell.

if bare fraction decreases then chop off the litter and soil c from the decreased fraction and add it to grsumlit & grsumsoc for spreading over the whole grid cell. if bare fraction increases then spread its litter and soil c uniformly over the increased fraction.

if a pft is not supposed to exist as indicated by pftexist and its fractional coverage is really small then get rid of the pft all together and spread its live and dead biomass over the grid cell.

adjust litter and soil c mass densities for increase in barefrac over the bare fraction.

spread litter and soil c over all pfts and the barefrac

get fcanmxs for use by class based on the new fcanmxs

update grid averaged vegetation biomass, and litter and soil c densities

and finally we check the c balance. we were supposed to use a fraction of npp for competition. some of it is used for expansion (this is what we save for allocation), and the rest becomes litter. so for each pft the total c mass in vegetation and litter pools must all add up to the same value as before competition.

check balance over the bare fraction

4.5 Ctem_params_initpftpars

4.6 Ctem_statevars

4.7 Disturbance_scheme_disturb

Canadian Terrestrial Ecosystem Model (CTEM) Disturbance Subroutine.

- subroutine, public `disturbance_scheme::disturb` (stemmass, rootmass, gleafmas, bleafmas, thliq, THL, W, THFC, uwind, vwind, lightng, fcancmx, litrmass, prbrhuc, rmatctem, extnprob, transientPOPD, il1, il2, sort, nol2pfts, grclarea, thice, popdin, lucemcom, dofir, currlat, iday, fsnow, isand,

4.7.1 Detailed Description

Canadian Terrestrial Ecosystem Model (CTEM) Disturbance Subroutine.

CTEM v. 2.0 represents disturbance as both natural and human-influenced fires. The original fire parametrization corresponding to CTEM v. 1.0 is described in [Arora20052ac]. The parametrization has since been adapted and used in several other DGVMs [Kloster2010-633] [Kloster2012-c79] [Migliavacca2013-eh] [Li20121c2]. CTEM v. 2.0 incorporates changes suggested in these studies as well as several new improvements.

Fire in CTEM is simulated using a process-based scheme of intermediate complexity that accounts for all elements of the fire triangle: fuel load, combustibility of fuel, and an ignition source. CTEM represents the probability of a fire occurrence (P_f), for a representative area of 500 km^2 (a_{rep}), as

$$P_f = P_b P_i P_m,$$

where the right hand side terms represent the fire probabilities that are conditioned on (i) the availability of biomass as a fuel source (P_b), (ii) the combustibility of the fuel based on its moisture content (P_m), and (iii) the presence of an ignition source (P_i). The probability of fire and the subsequent calculations are performed for each PFT present in a grid cell (but the PFT index α is omitted for clarity in Eq. fieya}). Since the CTEM parametrization is based on one fire per day per representative area, the representative area has to be sufficiently small that the requirement of only one fire per day is reasonable, yet sufficiently large such that it is not possible to burn the entire representative area in 1 day. Based on MODIS observed fire counts in Fig. 1 of [Li20121c2], 500 km^2 is an appropriate size to not have more than one fire per day and still be a large enough area to be assumed representative of the grid cell as a whole.

The P_b term depends on the aboveground biomass (B_{ag}) available for sustaining a fire (which includes the green and brown leaf mass, stem mass and litter mass, $B_{ag} = C_L + C_S + C_D$). Below a lower threshold of aboveground biomass (B_{low} ; 0.2 kg C m^{-2} ; similar to [Moorcroft2001-co], and [Kucharik2000-xk]), fire is not sustained and thus has a probability of 0. Above a biomass of 1.0 kg C m^{-2} (B_{high}), P_b is set to 1 as the amount of fuel available is assumed sufficient for fire. P_b is then calculated using the aboveground biomass, B_{ag} (kg C m^{-2}) with a linear variation between the upper and lower thresholds as

$$P_b = \max \left[0, \min \left(1, \frac{B_{ag} - B_{low}}{B_{high} - B_{low}} \right) \right].$$

The linear decrease of P_b from B_{high} to B_{low} reflects the fragmentation of fuel that occurs as biomass decreases. Fuel fragmentation impacts upon area burned as it impedes the fire spread rate [Guyette2002-rc].

The probability of fire based on the presence of ignition sources (P_i) is influenced by both natural (lightning) and anthropogenic agents (either intentional or accidental). An initial lightning scalar, ϑ_F , that varies between 0 and 1 is found as

$$\vartheta_F = \max \left[0, \min \left(1, \frac{F_{c2g} - F_{low}}{F_{high} - F_{low}} \right) \right],$$

where F_{low} and F_{high} represent lower and upper thresholds of cloud-to-ground lightning strikes (F_{c2g} , $\text{flashes km}^{-2} \text{ month}^{-1}$), respectively. Similar to Eq. (eqn:Pb)), below the lower threshold (F_{low} ; $0.25 \text{ flashes km}^{-2} \text{ month}^{-1}$), ϑ_F is 0 implying lightning strikes are not sufficient to cause fire ignition, above the upper threshold (F_{high} ; $10.0 \text{ flashes km}^{-2} \text{ month}^{-1}$) ϑ_F is 1, as ignition sources now do not pose a constraint on fire. The amount of cloud-to-ground lightning, F_{c2g} , is a fraction of the total lightning based on the relationship derived by [Price1993-fm] (approximation of their Eqs. 1 and 2) as

$$F_{c2g} = 0.22 \exp(0.0059 \times |\Phi|) F_{tot},$$

where Φ is the grid cell latitude in degrees and F_{tot} is the total number of lightning *flashes* $km^{-2} month^{-1}$ (both cloud-to-cloud and cloud-to-ground). The probability of fire due to natural ignition, $P_{i,n}$, depends on the lightning scalar, ϑ_F , as

$$P_{i,n} = y(\vartheta_F) - y(0)(1 - \vartheta_F) + \vartheta_F[1 - y(1)]y(\vartheta_F) = \frac{1}{1 + \exp\left(\frac{0.8 - \vartheta_F}{0.1}\right)}.$$

Fire probability due to ignition caused by humans, $P_{i,h}$, is parametrized following [Kloster2010-633] with a dependence on population density, p_d (*number of people* km^{-2})

$$P_{i,h} = \min \left[1, \left(\frac{p_d}{p_{thres}} \right)^{0.43} \right],$$

where p_{thres} is a population threshold (300 *people* km^{-2}) above which $P_{i,h}$ is 1. The probability of fire conditioned on ignition, P_1 , is then the total contribution from both natural and human ignition sources

$$P_1 = \max[0, \min\{1, P_{i,n} + (1 - P_{i,n})P_{i,h}\}].$$

The population data used to calculate probability of fire ignition caused by humans and anthropogenic fire suppression (discussed further down in this section) is based on the HYDE 3.1 data set [Klein_Goldewijk2010-lh]

The probability of fire due to the combustibility of the fuel, P_m , is dependent on the soil moisture in vegetation's root zone and in the litter layer. The root-zone soil wetness (ϕ_{root} , Eq. degsoilsat) is used as a surrogate for the vegetation moisture content and the soil wetness of the top soil layer as a surrogate for the litter moisture content. If a grid cell is covered by snow, P_m is set to zero. The probability of fire conditioned on soil wetness in vegetation's rooting zone, $P_{m,V}$, is then

$$P_{m,V} = 1 - \tanh \left[\left(\frac{1.75 \phi_{root}}{E_V} \right)^2 \right],$$

where E_V is the extinction soil wetness above which $P_{m,V}$ is reduced to near zero and is set to 0.30.

The probability of fire based on the moisture content in the *duff* layer, $P_{m,D}$, which includes the brown leaf mass (grasses only) and litter mass ($B_{duff} = C_{L,b} + C_D$; $kg C m^{-2}$), is calculated in a similar way but uses the soil wetness of the first soil layer, (ϕ_1 , Eq. phitheta), as a surrogate for the moisture in the duff layer itself as

$$P_{m,D} = 1 - \tanh \left[\left(\frac{1.75 \phi_1}{E_D} \right)^2 \right],$$

where the extinction soil wetness for the litter layer, E_D , is set to 0.50, which yields a higher probability of fire for the litter layer than for the vegetation for the same soil wetness. P_m is then the weighted average of $P_{m,V}$ and $P_{m,D}$ given by

$$P_m = P_{m,V}(1 - f_{duff}) + P_{m,D}f_{duff} = \frac{B_{duff}}{B_{ag}}$$

where f_{duff} is the duff fraction of aboveground combustible biomass.

The area burned (a) is assumed to be elliptical in shape for fires based upon the wind speed and properties of an ellipse

$$a(t) = \pi \frac{l}{2} \frac{w}{2} = \frac{\pi}{2} (v_d + v_u) v_p t^2,$$

where l (m) and w (m) are the lengths of major and minor axes of the elliptical area burnt; v_d ($km h^{-1}$) and v_u ($km h^{-1}$) are the fire spread rates in the downwind and upwind directions, respectively; v_p ($km h^{-1}$) is the fire spread rate perpendicular to the wind direction and t is the time (h).

The fire spread rate in the downwind direction (v_d) is represented as

$$v_d = v_{d,max} g(u) h(\phi_{r,d})$$

where $v_{d,max}$ ($km h^{-1}$) is the PFT-specific maximum fire spread rate from [Li2012c2], which is set to zero for crop PFTs (see also [ctem_params.f90](#)). The functions $g(u)$ accounts for the effect of wind speed and $h(\phi_{r,d})$ accounts for the effect of rooting zone and duff soil wetness on the fire spread rate, as discussed below.

The wind speed (u ; $km\ h^{-1}$) is used to determine the length (l) to breadth (w) ratio, L_b , of the elliptical area burned by fire

$$L_b = \frac{l}{w} = \frac{v_d + v_u}{2v_p} = 1 + 10[1 - \exp(-0.06u)]$$

and its head to back ratio, H_b , following [Li20121c2], as

$$H_b = \frac{v_d}{v_u} = \frac{L_b + (L_b^2 - 1)^{0.5}}{L_b - (L_b^2 - 1)^{0.5}},$$

which help determine the fire spread rate in the direction perpendicular to the wind speed and in the downward direction. Equations (lb) and (hb) are combined to estimate the wind scalar $g(u)$ as

$$g(u) = g(0) \frac{2.0L_b}{(1 + 1/H_b)} \frac{g(u)}{g(0)} = \frac{v_d}{v_p} = \frac{2.0L_b}{(1 + 1/H_b)},$$

which varies between 0.05 and 1. The lower limit is imposed by the $g(0)$ term, which has a value of 0.05 and represents the fire spread rate in the absence of wind ($u = 0$); the upper limit is assigned a maximum value of 1. The fire spread rate in the absence of wind is essentially the spread rate in the direction perpendicular to the wind speed (v_p). The value of the $g(0)$ term is derived by considering the case where the wind speed becomes very large. As $u \rightarrow \infty$ then $L_b \rightarrow 11$ and $H_b \rightarrow 482$, while $g(\infty) = 1$ due to its definition, which yields $g(0) = 0.0455 \approx 0.05$.

The dependence of fire spread rate on the rooting zone and duff soil wetness, $h(\phi_{r,d})$ is represented as

$$h(\phi_{r,d}) = h(\phi_{root})(1 - f_{duff}) + h(\phi_1)f_{duff}h(\phi_{root}) = \left(1 - \min\left(1, \frac{\phi_{root}}{E_V}\right)\right)^2 h(\phi_1) = \left(1 - \min\left(1, \frac{\phi_1}{E_D}\right)\right)^2.$$

Both $h(\phi_{root})$ and $h(\phi_1)$ gradually decrease from 1 (when soil wetness is 0 and soil moisture does not constrain fire spread rate) to 0 when soil wetness exceeds the respective extinction wetness thresholds, E_V and E_D .

With fire spread rate determined, and the geometry of the burned area defined, the area burned in 1 day, a_{1d} ($km^2\ day^{-1}$), following [Li20121c2], is calculated as

$$a_{1d} = \frac{\pi v_d^2 t^2}{4L_b} \left(1 + \frac{1}{H_b}\right)^2 = \frac{\pi v_d^2 (24^2)}{4L_b} \left(1 + \frac{1}{H_b}\right)^2$$

by setting t equal to 24 h .

The fire extinguishing probability, q , is used to calculate the duration (τ , $days$) of the fire, which in turn is used to calculate the area burned over the duration of the fire, $a_{\tau d}$. q is represented following [Kloster2010-633] as

$$q = 0.5 + \frac{\max[0, 0.9 - \exp(-0.025 p_d)]}{2},$$

which yields a value of q that varies from 0.5 to 0.95 as population density, p_d ($number\ of\ people\ km^{-2}$), increases from zero to infinity. Higher population density thus implies a higher probability of fire being extinguished. q represents the probability that a fire will be extinguished on the same day it initiated and the probability that it will continue to the next day is $(1 - q)$. Assuming individual days are independent, the probability that the fire will still be burning on day τ is $(1 - q)^\tau$. The probability that a fire will last exactly τ days, $P(\tau)$, is the product of the probability that the fire still exists at day τ and the probability it will be extinguished on that day hence $P(\tau) = q(1 - q)^\tau$. This yields an exponential distribution of fire duration whose expected value is

$$\bar{\tau} = E(\tau) = \sum_{\tau=0}^{\infty} \tau q(1 - q)^\tau = \frac{1 - q}{q}.$$

Based on this fire duration and the area burned in 1 day (Eq. a_{1d}), the area burned over the duration of the fire ($a_{\tau d}$) (but still implemented in 1 day since the model does not track individual fires over their duration, $km^2\ day^{-1}$) is calculated as

$$a_{\tau d} = E(a_{1d}\tau^2) = \sum_{\tau=0}^{\infty} a_{1d}\tau^2 q(1 - q)^\tau = a_{1d} \frac{(1 - q)(2 - q)}{q^2}.$$

Finally, and reintroducing the PFT index α , the area burned is extrapolated for a PFT α ($A_{b,\alpha}$, $km^2 day^{-1}$) to the whole grid cell as

$$A_{b,\alpha} = P_{f,\alpha} a_{\tau d,\alpha} \frac{A_g f_\alpha}{a_{rep}},$$

where A_g is area of a grid cell (km^2), f_α the fractional coverage of PFT α and a_{rep} the representative area of $500 km^2$, as mentioned earlier. Area burned over the whole grid cell (A_b , $km^2 day^{-1}$) is then calculated as the sum of area burned for individual PFTs,

$$A_b = \sum_{\alpha=1}^N A_{b,\alpha}.$$

Fire emits CO_2 , other trace gases, and aerosols as biomass is burned while plant mortality and damage due to fire contribute to the litter pool. The emissions of a trace gas/aerosol species j from PFT α , $E_{\alpha,j}$ ($gspecies(m^{-2}gridcellarea)day^{-1}$) are obtained from a vector of carbon densities $\vec{C}_\alpha = (C_L, C_S, C_R, C_D)_\alpha$ ($kg C m^{-2}$) for its leaf, stem, root and litter components, multiplied by a vector of combustion factors $mho_\alpha = (mho_L, mho_S, mho_R, mho_D)_\alpha$, which determines what fraction of leaf, stem, root and litter components gets burned, multiplied by a vector of emissions factors $\Upsilon_j = (\Upsilon_L, \Upsilon_S, \Upsilon_R, \Upsilon_D)_j$ ($gspecies(kg C dryorganicmatter)^{-1}$), and by the area burned $A_{b,\alpha}$ for that PFT.

The dot product of \vec{C}_α , Υ_j and mho_α thus yields emissions per unit grid cell area of species j from PFT α ,

$$E_{\alpha,j} = ((\vec{C}_\alpha \cdot mho_\alpha) \cdot \Upsilon_j) \frac{A_{b,\alpha}}{A_g} \frac{1000}{450},$$

where the constant 1000 converts \vec{C}_α from $kg C m^{-2}$ to $g C m^{-2}$ and the constant 450 ($g C (kg dryorganicmatter)^{-1}$) converts biomass from carbon units to dry organic matter [Li20121c2]. The corresponding loss of carbon ($kg C m^{-2} day^{-1}$) from the three live vegetation components (L, S, R) and the litter pool (D) of PFT α is given by

$$H_{\alpha,i} = C_{\alpha,i} mho_i \left(\frac{A_{b,\alpha}}{A_g} \right) \quad i = L, S, R, D.$$

The PFT-specific combustion factors for leaf (mho_L), stem (mho_S), root (mho_R) and litter (mho_D) components are summarized in [ctem_params.f90](#). Emission factors for all species of trace gases and aerosols (CO_2 , CO , CH_4 , H_2 , $NHMC$, NO_x , N_2O , total particulate matter, particulate matter less than $2.5 \mu m$ in diameter, and black and organic carbon) are based on an updated set by [Andreae2001-e04] listed in Tables 3 and 4 of [Li20121c2].

Litter generated by fire is based on similar mortality factors, which reflect a PFT's susceptibility to damage due to fire $\Theta_\alpha = (\Theta_L, \Theta_S, \Theta_R)_\alpha$ (fraction). The contribution to litter pool of each PFT due to plant mortality associated with fire ($kg C m^{-2} day^{-1}$) is calculated as

$$M_\alpha = (\vec{C}_\alpha \cdot \Theta_\alpha) \frac{A_{b,\alpha}}{A_g},$$

which is the sum of contribution from individual live vegetation pools

$$M_{\alpha,i} = C_{\alpha,i} \Theta_{\alpha,i} \left(\frac{A_{b,\alpha}}{A_g} \right) \quad i = L, S, R.$$

The carbon loss terms associated with combustion of vegetation components and litter ($H_{\alpha,i}$, $i = L, S, R, D$) and mortality of vegetation components ($M_{\alpha,i}$, $i = L, S, R$) due to fire are used in Eqs. (`rate_change_eqns_live_pools`) and (`rate_change_eqns_dead_pools`), which describe the rate of change of carbon in model's five pools (however, listed there without the PFT subscript α). The PFT-specific mortality factors for leaf (Θ_L), stem (Θ_S) and root (Θ_R) components are listed in [ctem_params.f90](#).

When CTEM is run with prescribed PFT fractional cover, the area of PFTs does not change and the fire-related emissions of CO_2 , other trace gases and aerosols, and generation of litter act to thin the remaining biomass. When competition between PFTs for space is allowed, fire both thins the remaining biomass and through plant mortality creates bare ground, which is subsequently available for colonization. The creation of bare ground depends on the susceptibility of each PFT to stand replacing fire (ζ_r , fraction) (see also [ctem_params.f90](#)) and the PFT area burned. The fire-related mortality rate, m_{dist} (day^{-1}), used in Eq. (`mortality`), is then

$$m_{dist,\alpha} = \zeta_{r,\alpha} \frac{A_{b,\alpha}}{f_\alpha A_g}.$$

After bare ground generation associated with fire, the thinned biomass is spread uniformly over the remaining fraction of a PFT. However, it is ensured that the carbon density of the remaining biomass does not increase to a value above what it was before the fire occurred.

4.7.2 Function/Subroutine Documentation

initialize required arrays to zero, or assign value

if not simulating fire, leave the subroutine now.

initialization ends

Find pft areas before

area in km^2

Find the probability of fire as a product of three functions with dependence on total biomass, soil moisture, and lightning

1. Dependence on total biomass

don't allow it to bring in crops since they are not allowed to burn.

Root biomass is not used to initiate fire. For example if the last fire burned all grass leaves, and some of the roots were left, its unlikely these roots could catch fire.

Find average biomass over the vegetated fraction

Sum up the vegetated area

calculate bterm for individual PFTs as well

1. Dependence on soil moisture

This is calculated in a way such that the more dry the root zone of a pft type is, and more fractional area is covered with that pft, the more likely it is that fire will get started. that is the dryness factor is weighted by fraction of roots in soil layers, as well as according to the fractional coverage of different pfts. the assumption here is that if there is less moisture in root zone, then it is more likely the vegetation will be dry and thus the likeliness of fire is more.

First find the dryness factor for each soil layer.

If there is snow on the ground, similarly if not soil, do not allow fire so set betadrgt to 0 for all soil layers otherwise calculate as per normal.

Now find weighted value of this dryness factor averaged over the rooting depth, for each pft

Next find this dryness factor averaged over the vegetated fraction $avgdryns(i) = avgdryns(i) + drgtstrs(i, j) * fcancmx(i, j)$

The litter and brown leaves are not affected by the soil water potential therefore they will react only to the moisture conditions (our proxy here is the upper soil moisture). If it is dry they increase the probability of fire corresponding to the proportion of total C they contribute. Only allow if there is no snow.

Use average root zone vegetation dryness to find likelihood of fire due to moisture.

calculate mterm for each PFT

duff fraction for each PFT, Vivek

$drgtstrs(i, j)$ is ϕ_{root} in Melton and Arora GMDD (2015) paper

no fire likelihood due to moisture if no vegetation

1. dependence on lightning

Dependence on lightning is modelled in a simple way which implies that a large no. of lightning flashes are more likely to cause fire than few lightning flashes.

New approximation of Price and Rind equation. It was developed from a more complete dataset than Prentice and Mackerras. Lightning comes in in units of $flashes/km^2/yr$ so divide by 12 to make per month.

Determine the probability of fire due to human causes this is based upon the population density from the .popd read-in file

————— Number of fire calculations —————\

This is not used in CTEM in general but we keep the code here for testing purposes

calculate natural and anthropogenic ignitions/km2.day the constant 0.25 assumes not all c2g lightning hits causes ignitions, only 0.25 of them do the constant (1/30.4) converts c2g lightning from flashes/km2.month to flashes/km2.day
MAKE SURE LIGHTNING IS IN UNITS OF FLASHES/KM2.MONTH

Eqs. (4) and (5) of Li et al. 2012 doi:10.5194/bg-9-2761-2012 + also see corrigendum

calculate fire suppression also as a function of population density. Li et al. (2012) formulation is quite similar to what we already use based on Kloster et al. (2010, I think) but we use Kloster's formulation together with our fire extinguishing probability. Here, the fire suppression formulation is just by itself

----- Number of fire calculations -----//

calculate fire probability for each PFT. Recall that lightning term is still grid averaged

----- Number of fire calculations -----\

This is not used in CTEM in general but we keep the code here for testing purposes

calculate total number of ignitions based natural and anthropogenic ignitions for the whole grid cell

finally calculate number of fire, noting that not all ignitions turn into fire because moisture and biomass may now allow that to happen, and some of those will be suppressed due to fire fighting efforts

----- Number of fire calculations -----//

Calculate area burned for each PFT, make sure it's not greater than the area available, then find area and fraction burned for the whole gridcell

soil moisture dependence on fire spread rate

wind speed, which is gridcell specific

Length to breadth ratio from Li et al. (2012)

head to back ratio from Li et al. (2012).

dependence of spread rate on wind

fire spread rate per PFT

area burned in 1 day for that PFT

fire extinguishing probability as a function of grid-cell averaged population density

account for low suppression in Savanna regions, see above for increase in ignition due to cultural practices

area multiplier to calculate area burned over the duration of the fire

per PFT area burned, km^2

Calculate gridcell area burned and fraction

Finally estimate amount of litter generated from each pft, and each vegetation component (leaves, stem, and root) based on their resistance to combustion. Update the veg pools due to combustion.

Set aside these pre-disturbance stem and root masses for use in burntobare subroutine.

Update the pools:

Output the burned area per PFT (the units here are burned fraction of each PFTs area. So if a PFT has 50% gridcell cover and 50% of that burns it will have a burnveg of 0.5 (which then translates into a gridcell fraction of 0.25). This units is for consistency outside of this subroutine.

If .not. dofired then we enter here and perform the calculations for the emissions since we might have some from luc.

We also estimate CO_2 emissions from each of these components. Note that the litter which is generated due to disturbance is uniformly distributed over the entire area of a given pft, and this essentially thins the vegetation biomass. If PFTCompetition is not on, this does not change the vegetation fractions, if competition is on a fraction will become bare. That is handled in burntobare subroutine called from competition subroutine.

Calculate the emissions of trace gases and aerosols based upon how much plant matter was burnt

Sum all pools that will be converted to emissions/aerosols (gc/m^2)

Add in the emissions due to luc fires (deforestation) the luc emissions are converted from $umolco_2m - 2s - 1togram - 2$ (day-1) before adding to tot_emit

Convert burnt plant matter from carbon to dry organic matter using a conversion factor, assume all parts of the plant has the same ratio of carbon to dry organic matter. units: $kgdom/m^2$

Convert the dom to emissions/aerosols using emissions factors units: $gspecies/m^2$

FLAG for the optimization of popd effect on fire I am taking the lterm out as the 'temp' var. So I have made tmp be dimension ilg and I overwrite the lterm (which is written to an output file) here in its place.

4.8 Disturbance_scheme_burntobare

- subroutine, public [disturbance_scheme::burntobare](#) (il1, il2, nilg, sort, pvgbioms, pgavltms, pgavscms, fcancmx, burnvegf, stemmass, rootmass, gleafmas, bleafmas, litrmass, soilcmas, pstemmass, pgleafmass, nppveg)

4.8.1 Detailed Description

4.8.2 Function/Subroutine Documentation

4.8.2.1 subroutine, public disturbance_scheme::burntobare (integer, intent(in) *il1*, integer, intent(in) *il2*, integer, intent(in) *nilg*, integer, dimension(icc), intent(in) *sort*, real, dimension(nilg), intent(in) *pvgbioms*, real, dimension(nilg), intent(in) *pgavltms*, real, dimension(nilg), intent(in) *pgavscms*, real, dimension(nilg,icc), intent(inout) *fcancmx*, real, dimension(nilg,icc), intent(in) *burnvegf*, real, dimension(nilg,icc), intent(inout) *stemmass*, real, dimension(nilg,icc), intent(inout) *rootmass*, real, dimension(nilg,icc), intent(inout) *gleafmas*, real, dimension(nilg,icc), intent(inout) *bleafmas*, real, dimension(nilg,iccp1), intent(inout) *litrmass*, real, dimension(nilg,iccp1), intent(inout) *soilcmas*, real, dimension(nilg,icc), intent(in) *pstemmass*, real, dimension(nilg,icc), intent(in) *pgleafmass*, real, dimension(nilg,icc), intent(inout) *nppveg*)

Parameters

in	<i>nilg</i>	no. of grid cells in latitude circle (this is passed in as either ilg or nlat depending on mos/comp)
in	<i>sort</i>	index for correspondence between 9 ctem pfts and size 12 of parameter vectors
in	<i>pvgbioms</i>	initial veg biomass
in	<i>pgavltms</i>	initial litter mass
in	<i>pgavscms</i>	initial soil c mass
in, out	<i>fcancmx</i>	initial fractions of the ctem pfts
in	<i>burnvegf</i>	per PFT fraction burned of that PFTs area
in, out	<i>gleafmas</i>	green leaf carbon mass for each of the 9 ctem pfts, kgc/m^2
in, out	<i>bleafmas</i>	brown leaf carbon mass for each of the 9 ctem pfts, kgc/m^2
in, out	<i>stemmass</i>	stem carbon mass for each of the 9 ctem pfts, kgc/m^2
in, out	<i>rootmass</i>	roots carbon mass for each of the 9 ctem pfts, kgc/m^2
in, out	<i>nppveg</i>	npp for individual pfts, $u - molco_2/m^2.sec$
in, out	<i>soilcmas</i>	soil carbon mass for each of the 9 ctem pfts + bare, kgc/m^2
in, out	<i>litrmass</i>	litter carbon mass for each of the 9 ctem pfts + bare, kgc/m^2
in	<i>pstemmass</i>	grid averaged stemmass prior to disturbance, kgc/m^2
in	<i>pgleafmass</i>	grid averaged rootmass prior to disturbance, kgc/m^2

Do some initializations

Account for disturbance creation of bare ground. This occurs with relatively low frequency and is PFT dependent. We must adjust the amount of bare ground created to ensure that we do not increase the density of the remaining vegetation.

Test the pftfrac to ensure it does not cause densification of the exisiting biomass Trees compare the stemmass while grass compares the root mass.

the pstemmass is from before the fire occurred, i.e. no thinning!

adjust the bare frac to accomodate for the changes

the pgleafmass is from before the fire occurred, i.e. no thinning!

adjust the bare frac to accomodate for the changes

Soil and litter carbon are treated such that we actually transfer the carbon to the bare fraction since it would remain in place as a location was devegetated In doing so we do not adjust the litter or soilc density on the remaining vegetated fraction. But we do adjust it on the bare fraction to ensure our carbon balance works out.

only do checks if we actually shifted fractions here.

check if total grid average biomass density is same before and after adjusting fractions
only do checks if we actually shifted fractions here.
then add the bare ground in.

4.9 Hetresg

Canadian Terrestrial Ecosystem Model (CTEM) Heterotrophic respiration Subroutine.

- subroutine, public [heterotrophic_respiration::hetresg](#) (litrmas, soilcmas, delzw,thpor,il1,il2,tbar,psisat, b,thliq,zbotw,thiceg,frac,isnow,isand,

4.9.1 Detailed Description

Canadian Terrestrial Ecosystem Model (CTEM) Heterotrophic respiration Subroutine.

Heterotrophic Respiration Subroutine For Bare Fraction

FLAG This needs to be edited for the peatland changes! Heterotrophic respiration, R_h ($\text{mol CO}_2 \text{ m}^{-2} \text{ s}^{-1}$), in CTEM is based on respiration from the litter (which includes contributions from the stem, leaf and root components), $R_{h,D}$, and soil carbon, $R_{h,H}$, pools,

$$R_h = R_{h,D} + R_{h,H}.$$

Heterotrophic respiration is regulated by soil temperature and moisture and is calculated on a daily time step. The original heterotrophic respiration scheme is described in [Arora2003-3b7] while the modified parametrization used in CTEM v. 2.0 is detailed in [Melton2014-xy] and is briefly described here. Respiration from the litter and soil carbon pools takes the following basic form

$$R_{h,i} = 2.64 \times 10^{-6} \varsigma_i C_i f_{15}(Q_{10}) f(\Psi)_i, i = D, H.$$

The soil carbon and litter respiration depends on the amount of carbon in these components (C_H and C_D ; kg C m^{-2}) and on a PFT-dependent respiration rate specified at 15°C (ς_H and ς_D ; $\text{kg C (kg C)}^{-1} \text{ yr}^{-1}$; see also [ctem_params.f90](#)). The constant 2.64×10^{-6} converts units from $\text{kg C m}^{-2} \text{ yr}^{-1}$ to $\text{mol CO}_2 \text{ m}^{-2} \text{ s}^{-1}$.

The effect of soil moisture is accounted for via dependence on soil matric potential ($f(\Psi)$), described later. The temperature dependency of microbial soil respiration rates has been estimated by several different formulations, ranging from simple Q_{10} (exponential) to Arrhenius-type formulations (see review by [Lloyd1994-ct]). In CTEM, soil temperature influences heterotrophic respiration through a temperature-dependent Q_{10} function ($f_{15}(Q_{10})$). The value of Q_{10} itself is assumed to be a function of temperature following a hyperbolic tan function:

$$Q_{10} = 1.44 + 0.56 \tanh[0.075(46.0 - T_i)], i = D, H,$$

where $T_{\{D,H\}}$ is the temperature of either the litter or soil carbon pool ($^\circ\text{C}$), respectively. The parametrization is a compromise between the temperature-independent Q_{10} commonly found in many terrestrial ecosystem models [Cox2001-am] and the temperature-dependent Q_{10} of [Kirschbaum1995-db]. While a constant Q_{10} yields an indefinitely increasing respiration rate with increasing temperature, the formulation of [Kirschbaum1995-db] gives a continuously increasing Q_{10} under decreasing temperature, which leads to unreasonably high soil and litter carbon pools at high latitudes in CTEM. The CTEM parametrization avoids these issues with a Q_{10} value of about 2.0 for temperatures less than 20°C , while a decreasing value of Q_{10} at temperatures above 20°C ensures that the respiration rate does not increase indefinitely.

The temperature of the litter pool is a weighted average of the temperature of the top soil layer (T_1) and the root temperature (T_R) as litter consists of leaf, stem, and root litter ($T_D = 0.7T_1 + 0.3T_R$). The temperature of the soil carbon pool is calculated as the mean soil temperature in the rooting zone based upon the fraction of roots in each soil layer and their temperature. The carbon in each soil layer is not explicitly tracked but assumed to adopt an exponential distribution [Jobbagy2000-pa].

The response of heterotrophic respiration to soil moisture is formulated through soil matric potential (Ψ ; MPa). While soil matric potential values are usually negative, the formulation uses absolute values to allow its logarithm to be taken. Absolute values of soil matric potential are high when soil is dry and low when it is wet. The primary premise of soil moisture control on heterotrophic respiration is that heterotrophic respiration is constrained both when the soils are dry (due to reduced microbial activity) and when they are wet (due to impeded oxygen supply to microbes) with optimum conditions in-between. The exception is the respiration from the litter component, which is assumed to be continually exposed to air, and thus never oxygen deprived, even when soil moisture content is high ($0.04 > |\Psi| \geq |\Psi_{sat}|$, where Ψ_{sat} is the soil matric potential at saturation). The soil moisture dependence thus varies between 0 and 1 with matric potential as follows:

for $0.04 > |\Psi| \geq |\Psi_{sat}|$

$$f(\Psi)_H = 1 - 0.5 \frac{\log(0.04) - \log |\Psi|}{\log(0.04) - \log |\Psi_{sat}|} f(\Psi)_D = 1;$$

for $0.06 \geq |\Psi| \geq 0.04$

$$f(\Psi)_{\{D, H\}} = 1;$$

for $100.0 \geq |\Psi| > 0.06$

$$f(\Psi)_{\{D, H\}} = 1 - 0.8 \frac{\log |\Psi| - \log(0.06)}{\log(100) - \log(0.06)};$$

for $|\Psi| > 100.0$

$$f(\Psi)_{\{D, H\}} = 0.2.$$

Heterotrophic respiration for bare ground is treated separately in CTEM. The carbon contributions to the bare ground litter and soil carbon pools come via processes such as creation of bare ground due to fire, competition between PFTs and land use change. The heterotrophic respiration is sensitive to temperature and moisture in the same manner as vegetated areas using Eqs. (lithet)–(lastpsi). The base respiration rates of $\zeta_{D,bare}$ and $\zeta_{H,bare}$ are set to 0.5605 and $0.02258 \text{ kg C (kg C)}^{-1} \text{ yr}^{-1}$, respectively.

The amount of humidified litter, which is transferred from the litter to the soil carbon pool ($C_{D \rightarrow H}$) is modelled as a fraction of litter respiration ($R_{h,D}$) as

$$C_{D \rightarrow H} = \chi R_{h,D}$$

where χ (see also [ctem_params.f90](#)) is the PFT-dependent humification factor and varies between 0.4 and 0.5. For crops, χ is set to 0.1 to account for reduced transfer of humidified litter to the soil carbon pool which leads to loss in soil carbon when natural vegetation is converted to croplands. Over the bare ground fraction χ is set to 0.45.

With heterotrophic respiration known, net ecosystem productivity (NEP) is calculated as

$$NEP = G_{canopy} - R_m - R_g - R_h.$$

4.9.2 Function/Subroutine Documentation

4.9.2.1 subroutine, public heterotrophic_respiration::hetresg (real, dimension(ilg,icc+1) *litrmass*, real, dimension(ilg,icc+1) *soilcmas*, real, dimension(ilg,ignd) *delzw*, real, dimension(ilg,ignd) *thpor*, integer *il1*, integer *il2*, real, dimension(ilg,ignd) *tbar*, real, dimension(ilg,ignd) *psisat*, real, dimension(ilg,ignd) *b*, real, dimension(ilg,ignd) *thliq*, real, dimension(ilg,ignd) *zbotw*, real, dimension(ilg,ignd) *thiceg*, real, dimension(ilg) *frac*, integer *isnow*, integer, dimension(ilg,ignd) *isand*)

Parameters

<i>il1</i>	il1=1
<i>il2</i>	il2=ilg
<i>isnow</i>	integer telling if bare fraction is fg (0) or fgs (1), isnow is changed to isnow(ilg) in classt of class version higher than 3.4 for coupling with ctem
<i>litrmass</i>	litter mass for the 8 pfts + bare in kgC/m^2
<i>soilcmas</i>	soil carbon mass for the 8 pfts + bare in kgC/m^2
<i>tbar</i>	soil temperature, k
<i>thliq</i>	liquid soil moisture content in 3 soil layers
<i>zbotw</i>	bottom of soil layers
<i>frac</i>	fraction of ground (fg) or snow over ground (fgs)
<i>psisat</i>	saturation matric potential
<i>b</i>	parameter b of clapp and hornberger
<i>thpor</i>	porosity

Estimate temperature of the litter and soil carbon pools.

We estimate the temperature of the soil c pool assuming that soil carbon over the bare fraction is distributed exponentially. note that bare fraction may contain dead roots from different pfts all of which may be distributed differently. For simplicity we do not track each pft's dead root biomass and assume that distribution of soil carbon over the bare fraction can be described by a single parameter.

find moisture scalar for soil c decomposition

find moisture scalar for litter decomposition

4.10 Hetresv

- subroutine, public [heterotrophic_respiration::hetresv](#) (fcan,fct, litrmass, soilcmas,delzw,thpor, il1,il2,tbar,psisat, b, thliq,roottemp,zbotw,sort,isand, thicec, ipeatland,

4.10.1 Detailed Description

4.10.2 Function/Subroutine Documentation

- 4.10.2.1 subroutine, public heterotrophic_respiration::hetresv (real, dimension(ilg,icc) *fcan*, real, dimension(ilg) *fct*, real, dimension(ilg,icc+1) *litrmass*, real, dimension(ilg,icc+1) *soilcmas*, real, dimension(ilg,ignd) *delzw*, real, dimension(ilg,ignd) *thpor*, integer *il1*, integer *il2*, real, dimension(ilg,ignd) *tbar*, real, dimension(ilg,ignd) *psisat*, real, dimension(ilg,ignd) *b*, real, dimension(ilg,ignd) *thliq*, real, dimension(ilg,icc) *roottemp*, real, dimension(ilg,ignd) *zbotw*, integer, dimension(icc) *sort*, integer, dimension(ilg,ignd) *isand*, real, dimension(ilg,ignd) *thicec*, integer, dimension(ilg) *ipeatland*)

Parameters

<i>il1</i>	il1=1
<i>il2</i>	il2=ilg
<i>sort</i>	index for correspondence between 9 pfts and 12 values in the parameters vectors
<i>fcan</i>	fractional coverage of ctem's 9 pfts
<i>fct</i>	sum of all fcan, fcan & fct are not used at this time but could be used at some later stage
<i>litrmass</i>	litter mass for the 9 pfts + bare in kgc/m^2
<i>tbar</i>	soil temperature, k
<i>soilcmas</i>	soil carbon mass for the 9 pfts + bare in kgc/m^2
<i>thliq</i>	liquid soil moisture content in 3 soil layers
<i>roottemp</i>	root temperature as estimated in mainres subroutine
<i>zbotw</i>	bottom of soil layers
<i>thicec</i>	liquid soil moisture content in 3 soil layers in canopy covered subarea
<i>psisat</i>	saturation matric potential
<i>b</i>	parameter b of clapp and hornberger
<i>thpor</i>	porosity

4.11 lo_driver_read_from_ctm

This subroutine reads in the restart/starting conditions from the .CTM file. The input values are checked and possibly adjusted if the run is intended to be with competition on and if the start_bare flag is true.

This subroutine reads in the restart/starting conditions from the .CTM file. The input values are checked and possibly adjusted if the run is intended to be with competition on and if the start_bare flag is true.

4.12 lo_driver_write_ctm_rs

After a set period is complete the restart file for CTEM (.CTM_RS) is written this restart file contains all of the CTEM level information needed to to restart the model to the same state.

After a set period is complete the restart file for CTEM (.CTM_RS) is written this restart file contains all of the CTEM level information needed to to restart the model to the same state.

4.13 lo_driver_create_outfiles

All output files are initialized in this subroutine.

All output files are initialized in this subroutine.

4.14 io_driver_class_monthly_aw

Accumulate and write out the monthly CTEM outputs.

- subroutine, public [io_driver::class_monthly_aw](#) (lonLocalIndex, latLocalIndex, IDAY, IYEAR, NCOUNT, NDAY, SBC, DELT, nltest, nmtest, TFREZ, ACTLYR, FTABLE, lastDOY)

4.14.1 Detailed Description

Accumulate and write out the monthly CTEM outputs.

4.14.2 Function/Subroutine Documentation

- 4.14.2.1 subroutine, public [io_driver::class_monthly_aw](#) (integer, intent(in) *lonLocalIndex*, integer, intent(in) *latLocalIndex*, integer, intent(in) *IDAY*, integer, intent(in) *IYEAR*, integer, intent(in) *NCOUNT*, integer, intent(in) *NDAY*, real, intent(in) *SBC*, real, intent(in) *DELT*, integer, intent(in) *nltest*, integer, intent(in) *nmtest*, real, intent(in) *TFREZ*, real, dimension(nlat,nmos), intent(in) *ACTLYR*, real, dimension(nlat,nmos), intent(in) *FTABLE*, integer, intent(in) *lastDOY*)

Accumulate output data for monthly averaged fields for class grid-mean. for both parallel mode and stand alone mode

4.15 io_driver_class_annual_aw

- subroutine, public `io_driver::class_annual_aw` (`lonLocalIndex`, `latLocalIndex`, `IDAY`, `IYEAR`, `NCOUNT`, `NDAY`, `SBC`, `DELT`, `nltest`, `nmtest`, `ACTLYR`, `FTABLE`, `lastDOY`)

4.15.1 Detailed Description

4.15.2 Function/Subroutine Documentation

- 4.15.2.1 subroutine, public `io_driver::class_annual_aw` (`integer, intent(in) lonLocalIndex`, `integer, intent(in) latLocalIndex`, `integer, intent(in) IDAY`, `integer, intent(in) IYEAR`, `integer, intent(in) NCOUNT`, `integer, intent(in) NDAY`, `real, intent(in) SBC`, `real, intent(in) DELT`, `integer, intent(in) nltest`, `integer, intent(in) nmtest`, `real, dimension(nlat,nmos)`, `integer, intent(in) ACTLYR`, `real, dimension(nlat,nmos)`, `integer, intent(in) FTABLE`, `integer, intent(in) lastDOY`)

Accumulate output data for yearly averaged fields for class grid-mean. for both parallel mode and stand alone mode

ADD INITIALIZATION FOR YEARLY ACCUMULATED ARRAYS

IDAY.EQ.365/366 .AND. NDAY

4.16 io_driver_ctem_daily_aw

Accumulate and write out the daily CTEM outputs.

- subroutine, public [io_driver::ctem_daily_aw](#) (nlttest, nmtest, iday, FAREROT, iyear, jdstd, jdsty, jdennd, jdendy, grclarea, onetile_perPFT, ipeatlandrow)

4.16.1 Detailed Description

Accumulate and write out the daily CTEM outputs.

4.16.2 Function/Subroutine Documentation

4.16.2.1 subroutine, public `io_driver::ctem_daily_aw` (integer, intent(in) *nlttest*, integer, intent(in) *nmtest*, integer, intent(in) *iday*, real, dimension(:,:), intent(in) *FAREROT*, integer, intent(in) *iyear*, integer, intent(in) *jdstd*, integer, intent(in) *jdsty*, integer, intent(in) *jdennd*, integer, intent(in) *jdendy*, real, dimension(:), intent(in) *grclarea*, logical, intent(in) *onetile_perPFT*, integer, dimension(:,:), intent(in) *ipeatlandrow*)

write daily ctem results

Reset the grid and tile average variables.

First some unit conversions:

Now for the bare fraction of the grid cell.

Aggregate to the tile avg vars:

Do the bare ground also:

Calculation of grid averaged variables

Write daily ctem results

First the per PFT values to file .CT01D

File: .CT01D

File .CT02D

File *.CT03D

File .CT04D

File *.CT06D

Now write out the bare fraction values (only needed if you have vars that are affected by barefrac values)

File: .CT01D

File *.CT03D

Now write out the tile average values for each tile if the tile number is greater than 1 (nmtest > 1).

File: .CT01D

File .CT02D

File .CT03D

File .CT04D

Finally do the grid avg values:

Accumulate yearly outputs

Accumulate the variables at the per PFT level

Also do the bare fraction amounts

Accumulate the variables at the per tile level

The pools are looked at just at the end of the year.

Add values to the per tile vars

Add values to the per gridcell vars

Write to annual output files:

First write out the per gridcell values

Write out the per tile values

Reset all annual vars in preparation for next year

4.19 lo_driver_close_outfiles

4.20 Landuse_change_initialize_luc

Canadian Terrestrial Ecosystem Model (CTEM) LUC Initial Read-In Subroutine.

- subroutine, public `landuse_change::initialize_luc` (*iyear*, *nmtest*, *nltest*, *no2pfts*, *cyclemet*, *cylycyr*, *lucyr*, *fcancrow*, *farerow*, *nfcancmxrow*, *pfcancmxrow*, *fcancmxrow*, *reach_eof*, *start_bare*, *PFTCompetition*, *onetile_perPFT*)

4.20.1 Detailed Description

Canadian Terrestrial Ecosystem Model (CTEM) LUC Initial Read-In Subroutine.

4.20.2 Function/Subroutine Documentation

4.20.2.1 subroutine, public `landuse_change::initialize_luc` (*integer*, intent(in) *iyear*, *integer*, intent(in) *nmtest*, *integer*, intent(in) *nltest*, *integer*, dimension(ican), intent(in) *no2pfts*, *logical*, intent(in) *cyclemet*, *integer*, intent(in) *cylycyr*, *integer*, intent(out) *lucyr*, *real*, dimension(nlat,nmos,icp1), intent(inout) *fcancrow*, *real*, dimension(nlat,nmos), intent(inout) *farerow*, *real*, dimension(nlat,nmos,icc), intent(out) *nfcancmxrow*, *real*, dimension(nlat,nmos,icc), intent(out) *pfcancmxrow*, *real*, dimension(nlat,nmos,icc), intent(out) *fcancmxrow*, *logical*, intent(inout) *reach_eof*, *logical*, intent(in) *start_bare*, *logical*, intent(in) *PFTCompetition*, *logical*, intent(in) *onetile_perPFT*)

Parameters

<i>in</i>	<i>onetile_perpft</i>	if you are running with one tile per PFT in mosaic mode, set to true. Changes how competition is run. Specifically it allows competition between tiles. This is not recommended for any case where you don't have one PFT in each tile as it has not been tested for that.
-----------	-----------------------	--

Initialize barefraction to 1.0

reset the composite *fcancrow* as it is appended on later in a loop

it is the first year, so prepare the *luc* data:

open the *luc* file

Skip first three rows:

get first year of *luc* data note we load the *nfcancmx*, not *pfcancmx* array. this is because this *nfcancmx* value is passed to the *pfcancmx* array at the start of each simulation year

next update our *luc* data if either of the following conditions are met:

1) we are cycling the met data and the *luc* year we just read in is less than the year we want to cycle over (assuming it is not defaulted to -9999) or,

2) we are not cycling over the met data so we just want to get the same year of *luc* data as the met data we read in above in preparation for our transient run.

If you are running with *start_bare* on, take in only the crop fractions, set rest to seed. If *PFTCompetition*, but not *start bare*, then just make sure you have at least seed for each pft.

not starting bare, but still make sure you have at least seed

Keep track of the non-crop *nfcancmx* for use in loop below. *pftarrays* keeps track of the *nfcancmxrow* for all non-crops *indexposj* and *indexposm* store the index values of the non-crops in a continuous array for use later. *n* and *k* are then the indexes used by these arrays.

check that in making these seed fraction we haven't made our total fraction more than 1.0.

Find out which of the non-crop PFTs covers the largest area.

j is then the *nmos* index and *m* is the *icc* index of the PFT with the largest area

Reduce the most dominant PFT by barf and minbare. The extra amount is to ensure we don't have trouble later with an extremely small bare fraction. barf is a negative value.

Find out which of the non-crop PFTs covers the largest area.

j is then the nmos index and m is the icc index of the PFT with the largest area

Reduce the most dominant PFT by barf and minbare. The extra amount is to ensure we don't have trouble later with an extremely small bare fraction. barf is a negative value.

get fcans for use by class using the nfcancmxs just read in

this tile has some plants so overwrite the seed fraction with an actual fraction

note: the seed fraction has already been assigned in runclassstem prior to entering this subroutine.

(re)find the bare fraction for farerow(i,iccp1)

check that the bare fraction is possible (>0) and if not then reduce the other pfts proportionally to make a non-negative bare ground fraction.

competition requires a 'seed' fraction so make sure the bare ground is also that big. for prescribed runs you just need it to be possible (>0).

assign the present pft fractions from those just read in

back up one year in the luc file this is because we were setting things up here, we will later call readin_luc so want the file to be rewound prior to that to the proper start year.

end of the luc file is reached. close and tell main program to exit

4.21 Landuse_change_readin_luc

Canadian Terrestrial Ecosystem Model (CTEM) LUC Annual Read-In Subroutine.

- subroutine, public `landuse_change::readin_luc` (iyear, nmtest, nlttest, lucyr, nfcancmxrow, pfcancmxrow, reach_eof, PFTCompetition, onetile_perPFT)

4.21.1 Detailed Description

Canadian Terrestrial Ecosystem Model (CTEM) LUC Annual Read-In Subroutine.

4.21.2 Function/Subroutine Documentation

4.21.2.1 subroutine, public `landuse_change::readin_luc` (integer, intent(in) *iyear*, integer, intent(in) *nmtest*, integer, intent(in) *nlttest*, integer, intent(inout) *lucyr*, real, dimension(nlat,nmos,icc), intent(out) *nfcancmxrow*, real, dimension(nlat,nmos,icc), intent(in) *pfcancmxrow*, logical, intent(inout) *reach_eof*, logical, intent(in) *PFTCompetition*, logical, intent(in) *onetile_perPFT*)

Parameters

in	<i>onetile_perpft</i>	if you are running with one tile per PFT in mosaic mode, set to true. Changes how competition is run. Specifically it allows competition between tiles. This is not recommended for any case where you don't have one PFT in each tile as it has not been tested for that.
----	-----------------------	--

it is subsequent years so read in and adjust the luc file info.

If PFTCompetition is on, then only take in the crop fraction. Set the other fractions to the same as before. These will be adjusted in `adjust_luc_fracs`.

(re)find the bare fraction for `farerow(i,iccp1)`

end of the luc file is reached. close and tell main program to exit

4.22 Landuse_change_luc

Canadian Terrestrial Ecosystem Model (CTEM) Land Use Change Subroutine.

- subroutine, public `landuse_change::luc` (il1,il2,nilg,nol2pfts,grclarea, pfcancmx, nfcancmx,iday,todfrac, yesfrac, interpol, PFTCompetition, leapnow,

4.22.1 Detailed Description

Canadian Terrestrial Ecosystem Model (CTEM) Land Use Change Subroutine.

The land use change (LUC) module of CTEM is based on (Arora and Boer, 2010) [Arora2010-416] and briefly described here. When the area of crop PFTs changes, CTEM generates LUC emissions. In the simulation where fractional coverage of PFTs is specified, the changes in fractional coverage of crop PFTs are made consistent with changes in the fractional coverage of natural non-crop PFTs. That is, an increase or decrease in the area of crop PFTs is associated with a corresponding decrease or increase in the area of non-crop PFTs. This approach is taken by [Wang2006-he], which allows one to reconstruct historical land cover given a spatial data set of changes in crop area over the historical period and an estimate of potential natural land cover for the pre-industrial period (as described in Sect. methods}). When competition between PFTs for space is allowed, only the fractional coverage of crop PFTs is specified. Similar to a simulation with prescribed PFT fractions, when the area of crop PFTs increases, the fractional coverage of non-crop PFTs is decreased in proportion to their existing coverage [Wang2006-he]. Alternatively, and in contrast to the simulation with prescribed PFT fractions, when the area of crop PFTs decreases then the generated bare fraction is available for recolonization by non-crop PFTs.

A decrease in the area of natural non-crop PFTs, associated with an increase in area of crop PFTs, results in deforested biomass (while the term *deforested* implies clearing of forests, the same processes can occur in grasslands as well and is meant here to imply removal of the biomass). The deforested biomass is divided into three components: (i) the component that is combusted or used for fuel wood immediately after natural vegetated is deforested and which contributes to atmospheric CO_2 , (ii) the component left as slash or used for pulp and paper products and (iii) the component that is used for long-lasting wood products. The fractions allocated to these three components depend on whether the PFTs are woody or herbaceous and on their aboveground vegetation biomass density (see Table 1 of [Arora2010-416]). To account for the timescales involved, the fraction allocated to slash or pulp and paper products is transferred to the model's litter pool and the fraction allocated to long-lasting wood products is allocated to the model's soil carbon pool. Land use change associated with a decrease in the area of natural vegetation thus redistributes carbon from living vegetation to dead litter and soil carbon pools and emits CO_2 to the atmosphere through direct burning of the deforested biomass. The net result is positive LUC carbon emissions from land to the atmosphere.

When croplands are abandoned, the area of natural PFTs increases. In simulations with prescribed fractional coverage of PFTs this results in a decreased carbon density for all model pools as the same amount of carbon is spread over a larger fraction of the grid cell. This reduced density implies that natural vegetation is able to take up carbon as it comes into equilibrium with the driving climate and atmospheric CO_2 concentration. This creates the carbon sink associated with abandonment of croplands as natural vegetation grows in its place. In simulations with competition between PFTs, the abandoned land is treated as bare ground, which is subsequently available for recolonization, as mentioned above. As natural vegetation expands into bare ground it takes up carbon, again creating the carbon sink associated with abandonment of croplands. The net result is negative LUC carbon emissions as carbon is taken from atmosphere to grow vegetation over the area that was previously a cropland.

4.22.2 Function/Subroutine Documentation

- 4.22.2.1 subroutine, public `landuse_change::luc` (integer il1, integer il2, integer nilg, integer, dimension(ican) nol2pfts, real, dimension(nilg) grclarea, real, dimension(nilg,icc) pfcancmx, real, dimension(nilg,icc) nfcancmx, integer iday, real, dimension(nilg,icc) todfrac, real, dimension(nilg,icc) yesfrac, logical interpol, logical PFTCompetition, logical leapnow)

Parameters

<i>il1</i>	il1=1
<i>il2</i>	il2=nilg
<i>nilg</i>	no. of grid cells in latitude circle(this is passed in as either ilg or nlat depending on comp/mos)
<i>iday</i>	day of year
<i>nol2pfts</i>	number of level 2 pfts
<i>leapnow</i>	true if this year is a leap year. Only used if the switch 'leap' is true.
<i>interpol</i>	if todfrac & yesfrac are provided then interpol must be set to false so that this subroutine doesn't do its own interpolation using pfcancmx and nfcancmx which are year end values
<i>pftcompetition</i>	true if the competition subroutine is on.
<i>pfcancmx</i>	previous max. fractional coverages of ctem's 9 pfts.
<i>nfcancmx</i>	next max. fractional coverages of ctem's 9 pfts.
<i>todfrac</i>	today's fractional coverage of all pfts
<i>yesfrac</i>	yesterday's fractional coverage of all pfts
<i>grclarea</i>	gcm grid cell area, km2

Constants and parameters are located in [ctem_params.f90](#)

find/use provided current and previous day's fractional coverage if competition is on, we will adjust these later.

perform interpolation

use provided values but still check they are not -ve

If competition is on, we need to adjust the other fractions for the increase/decrease in cropland as only the crops areas is now specified.

check if this year's fractional coverages have changed or not for any pft

initialization ends

if land use change has taken place then get fcanmxs for use by class based on the new fcanmxs

check if the interpol didn't mess up the barefrac. if so, take the extra amount from the pft with the largest area. jm
apr 24 2013. but you can't take it from crops!

find previous day's bare fraction using previous day's fcanmxs

check if the interpol didn't mess up the pbarefra. if so, take the extra amount from the pft with the largest area. jm
apr 24 2013. but you can't take it from crops!

based on sizes of 3 live pools and 2 dead pools we estimate the total amount of c in each grid cell.

find above ground biomass and treatment index for combust, paper,
and furniture

check if a pft's fractional cover is increasing or decreasing

check if bare fraction increases or decreases

if the fractional coverage of pfts increases then spread their live & dead biomass uniformly over the new fraction.
this effectively reduces their per m2 c density.

if bare fraction increases then spread its litter and soil c uniformly over the increased fraction

if any of the pfts fractional coverage decreases, then we chop the aboveground biomass and treat it according to our rules (burn it, and convert it into paper and furniture). the below ground live biomass and litter of this pfts gets assimilated into litter of all pfts (uniformly spread over the whole grid cell), and soil c from the chopped off fraction of this pft, gets assimilated into soil c of all existing pfts as well.

chop off above ground biomass

rootmass needs to be chopped as well and all of it goes to the litter/paper pool

keep adding chopped off biomass for each pft to get the total for a grid cell for diagnostics

find what's burnt, and what's converted to paper & furniture

keep adding all this for a given grid cell

litter from the chopped off fraction of the chopped off pft needs to be assimilated, and so does soil c from the chopped off fraction of the chopped pft

if bare fraction decreases then chop off the litter and soil c from the decreased fraction and add it to grsumlit & grsumsoc for spreading over the whole grid cell

calculate if the chopped off biomass equals the sum of grsumcom(i), grsumpap(i) & grsumfur(i)

spread chopped off stuff uniformly over the litter and soil c pools of all existing pfts, including the bare fraction.

convert the available c into density

the combusted c is used to find the c flux that we can release into the atmosphere.

this is flux in kg c/m².day that will be emitted

convert all land use change fluxes to u-mol co₂-c/m².sec

and finally we see if the total amount of carbon is conserved

total litter mass (before + input from chopped off biomass) and after must be same

for conservation totcmass(i) must be equal to ntotcmass(i) plus combustion carbon losses

update grid averaged vegetation biomass, and litter and soil c densities

just like total amount of carbon must balance, the grid averaged densities must also balance

4.23 Landuse_change_adjust_luc_fracs

this subroutine adjusts the amount of each pft to ensure that the fraction of gridcell bare ground is >0 .

4.23.1 Detailed Description

this subroutine adjusts the amount of each pft to ensure that the fraction of gridcell bare ground is >0 .

4.24 Landuse_change_adjust_fracs_comp

This subroutine is used when PFTCompetition = true. It adjusts the amount of each pft to allow expansion of cropland.

4.24.1 Detailed Description

This subroutine is used when PFTCompetition = true. It adjusts the amount of each pft to allow expansion of cropland.

4.25 Moss_photosynthesis

Moss photosynthesis subroutine.

- subroutine, public `peatlands_mod::mossph` (il1, il2, iday, qswnv, thliq, co2conc, tsurfk, zsnow, pres, Ccross-mas, dmoss, anmoss, rmlmoss, cevapmoss, ievapmoss, ipeatland, daylength, pdd)

4.25.1 Detailed Description

Moss photosynthesis subroutine.

Mosses are an important contributor to the primary production and the C sequestration in peatlands, owing to the low decomposability of the moss tissue. Sphagnum in peatlands grows at 20–1600 g biomass m⁻²/yr and accounts for about 50 % of the total peat volume (Turetsky, 2003). We have modified CTEM to include a moss C pool and moss litter pool along with the related C fluxes, i.e. photosynthesis, autotrophic respiration, heterotrophic respiration, and humification. The net photosynthesis of moss (G_m) is calculated from the gross photosynthesis ($G_{0,m}$) and dark respiration ($R_{d,m}$):

$$G_m = G_{0,m} - R_{d,m}.$$

The moss photosynthesis and dark respiration are calculated using the Farquhar~(1989) biochemical approach following the MWM (St-Hilaire et al., 2010) **[St-Hilaire2010-5e9]** and CTEM (Melton and Arora, 2016) **[Melton2016-zx]**, with modifications for integration with CLASS–CTEM and moss phenology. The leaf-level gross photosynthesis rate $G_{0,m}$ (μ mol CO₂ /m²/s) is obtained as the minimum of the transportation limited photosynthesis rates (J_s) and the first root of the quadratic solution of the light-limited rate (J_e) and the Rubisco limited rate (J_c). A logistic factor (ς) is added with values 0 or 1 to introduce a seasonal control of moss photosynthesis. In the MWM, spring photosynthesis starts when the snow depth is below 0.05 m and the soil temperature at 5 cm depth goes above 0.5 C (Moore et al., 2006). Since in our case CLASS sets the minimum depth for melting, discontinuous snow to 0.10 m, this limits the spring photosynthesis to starting only once the snow is completely melted.

$$G_{0,m} = \varsigma \min \left(J_s, \frac{(J_c + J_e) \pm \sqrt{(J_c + J_e)^2 - 4(J_c + J_e)}}{2} \right)$$

The dark respiration in mosses ($R_{d,m}$) is calculated as a function of the base dark respiration rate ($R_{d,m,0}$), which has a value of 1.1 (μ mol CO₂ /m²/s) (Adkinson and Humphreys, 2011) scaled by the moss moisture ($f_{m,rd}$) and soil temperature functions ($f_{T,rd}$). The moss moisture function is based on the volumetric water content of the moss, θ_m (kg water / (kg dry mass)). The MWM models the relation between water content in mosses and dark respiration with optimal water content at 5.8 g water per g dry weight, following the approach in Frolking et al. (1996). We modified the relation for water content above the optimal water content, based on a recent discovery of a weak linear positive relation between the dark respiration rate and the water content above the optimal water content during the late summer and fall (Adkinson and Humphreys, 2011):

$$R_{d,m} = R_{d,m,0} f_{m,rd} f_{T,rd}$$

$$f_{T,rd} = (3.22 - (0.046 \cdot T_{moss}))^{(T_{moss} - 25/10)}$$

$$f_{m,rd} = 0 \text{ for } \theta_m < 0.4$$

$$f_{m,rd} = 0.35\theta_m^{2/3} - 0.14 \text{ for } 0.4 \leq \theta_m < 5.8$$

$$f_{m,rd} = 0.01\theta_m + 0.942 \text{ for } 5.8 < \theta_m$$

Photosynthetic photon flux density (PPFD) is measured by the photosynthetically active radiation (PAR), which is defined as the solar radiation between 0.4 to 0.7 μ mol that can be used by plants via photosynthesis. In the coupled CLASS–CTEM system, the PAR received by the moss (PAR_m, unit μ mol photons m⁻²/s) is converted from the visible short-wave radiation reaching the ground (K_{*g} , unit W/m²) in CLASS by a factor of 4.6 μ mol /m²/s per W/m² (McCree, 1972). K_{*g} is a function of the incoming short-wave radiation ($K \downarrow$, unit: W/m²), the surface albedo (α_g), and the canopy transmissivity (τ_c):

$$K_{*g} = K \downarrow \tau_c (1 - \alpha_g)$$

The energy uptake by the moss layer is thus a function of the total incoming short-wave radiation, the aggregated LAI of the PFTs present, the snow depth, the fractional vegetation cover, and the soil water content (Versegny, 2012). In peatland C models that do not consider vegetation dynamics, the transmissivity of the vegetation canopy

is usually assumed to be constant (e.g. St-Hilaire et al., 2010) [St-Hilaire2010-5e9]. Compared with such models, CLASS enables a more detailed representation of light incident on the moss surface since it includes partitioning of direct/diffuse and visible/near-IR radiation, PFT-specific transmissivities, and time-varying LAI and fractional PFT coverages (Versegny, 2012) [Versegny2012-c0e].

4.25.2 Function/Subroutine Documentation

4.25.2.1 subroutine, public peatlands_mod::mossph (integer, intent(in) *il1*, integer, intent(in) *il2*, integer, intent(in) *iday*, real, dimension(ilg), intent(in) *qswnv*, real, dimension(ilg,ignd), intent(in) *thliq*, real, dimension(ilg), intent(in) *co2conc*, real, dimension(ilg), intent(in) *tsurfk*, real, dimension(ilg), intent(in) *zsnow*, real, dimension(ilg), intent(in) *pres*, real, dimension(ilg), intent(in) *Cmossmas*, real, dimension(ilg), intent(in) *dmoss*, real, dimension(ilg), intent(out) *anmoss*, real, dimension(ilg), intent(out) *rmlmoss*, real, dimension(ilg), intent(out) *cevapmoss*, integer, dimension(ilg), intent(out) *ievapmoss*, integer, dimension(ilg), intent(in) *ipeatland*, real, dimension(ilg), intent(in) *daylength*, real, dimension(ilg), intent(inout) *pdd*)

Parameters

in	<i>qswnv</i>	visible short wave radiation = qswnv in TSOLVE and qswnv in TSOLV↔ C (W/m2)
in	<i>tsurfk</i>	grid average ground surface temprature in K
in	<i>cmossmas</i>	unit kg moss C updated in ctem
in	<i>dmoss</i>	unit m, depth of living moss. assume = 2 cm can be related to mmoss as a variable
out	<i>ievapmoss</i>	Value is 0 is no evaporation from moss, 1 otherwise
out	<i>anmoss</i>	net photosynthesis (umol CO2/m2/s)
out	<i>rmlmoss</i>	moss autotrophic respiration (umol CO2/m2/s)
out	<i>cevapmoss</i>	evaporation coefficient for moss surface

phenology water factor on mosses ,grow when temperature > -4.0 and snowpack < 0.15 m

4.26 Peat_soil_het_resp

Peatland soil heterotrophic respiration.

- subroutine, public [peatlands_mod::hetres_peat](#) (il1, il2, ipeatland, isand, litrmsmoss, peatdep, wtable, tbar, thliq, thice, thpor, bi, zbotw, delzw, psisat, litresms, socresp, resoxic, resanoxic)

grid average peat soil heterotrophic respiration subroutine

4.26.1 Detailed Description

Peatland soil heterotrophic respiration.

Over the non-peatland fraction, HR is calculated as the sum of the respiration from litter and soil carbon pools as in the original version of CTEM (Arora, 2003). The soil C pool over the non-peatland areas is assumed to be exponentially distributed with depth (Arora, 2003). In peatlands a large amount of humic soil is generally located in the permanently saturated zone and the bulk density increases with soil depth (Loisel and Garneau, 2010). Thus, the assumption of exponentially decreasing distribution of C content with increasing soil depth is not valid in peatlands. We used a quadratic equation to calculate the distribution of soil C content over depth based on an empirically determined bulk density profile (Frolking et al., 2001).

HR over the peatland fraction of a grid cell is modelled using a two-pool approach with a flexible boundary between the pools that depends on the depth of the water table:

$$R_o = C_{SOM,o} k_o f_{T,o}$$

$$R_a = C_{SOM,a} k_a f_{T,a} f_{anoxic}$$

where o and a denote the oxic and anoxic portions of the soil C pool respectively. The respiration rate R (unit: $\mu\text{mol C m}^{-2} / \text{s}$) is obtained from the respiration rate coefficient ($\$ \text{ mol C} / \text{kg C} / \text{s}$), the temperature functions f_T , the soil C mass C_{SOM} (kg), and a scaling factor f_{anoxic} after Frolking et al. (2010, 2001), which represents the inhibition of microbial respiration under anoxic conditions. The value of this parameter is uncertain, varying in those two papers between 0.001, 0.025 and 0.1. Based on calibration runs using two of the data sets described below (MB-Bog and AB-Fen), we adopted a value of 0.025. Q_{10} is calculated using a hyperbolic tan function of the soil temperatures (T_s) of the oxic and anoxic zones (Melton and Arora, 2016), which are in turn functions of water table depth. The Q_{10} values of the anoxic and the oxic zones of the soil are indicated as $Q_{10,a}$ and $Q_{10,o}$. The values of k , f_T , and C_{SOM} are updated along with the water table depth (z_{wt} , unit: m, positive downward) and the peat depth (z_p , unit: m) at each CTEM time step. The equations for Q_{10} and C_{SOM} are derived from Fig. 2 in Frolking et al. (2001), and parameterized differently for fens and bogs :

$$f_{T,o} = Q_{10,o}^{\left(\int_0^{z_{wt}} T_j - 15 \right) / 10}$$

$$f_{T,a} = Q_{10,a}^{\left(\int_{z_{wt}}^{z_p} T_j - 15 \right) / 10}$$

$$Q_{10} = 1.44 + 0.56 \tanh[0.075 (46.0 - T_s)]$$

$$T_{s,o} = \int_0^{z_{wt}} T_j / (z_{wt})$$

$$T_{s,a} = \int_{z_{wt}}^{z_p} T_j / (z_p - z_{wt})$$

$$k_o = 0 \text{ for } z_{wt} < 0$$

$$k_o = k_1 (1 - e^{k_2 z_{wt}}) + k_3 z_{wt} \text{ for } 0.3 > z_t \geq 0$$

$$k_4 e^{k_5 z_{wt}} + k_6 z_{wt} + k_7 \text{ for } z_{wt} \geq 0.3$$

$$k_a = k_4 e^{k_5 z_p} + 10 k_6 z_p + k_7 \text{ for } z_{wt} < 0$$

$$k_a = | k_1 e^{k_2 z_{wt}} - k_4 e^{k_5 z_p} - k_3 z_{wt} + k_8 \text{ for } 0.3 > z_{wt} \geq 0$$

$$k_a = k_4 (e^{k_5 z_p} - e^{k_5 z_{wt}}) + k_6 (z_p - z_{wt}) \text{ for } z_{wt} \geq 0.3$$

$$C_{SOM,o} = 0.487 * (k_9 z_{wt}^2 + k_{10} z_{wt})$$

$$C_{SOM,a} = C_{SOM} - C_{SOM,o}$$

where 0.487 is a parameter that converts from soil mass to soil C content. The variation of k_o and k_a with water table depth for bogs and fens is shown in Fig. 2 of (Wu et al. 2016) [Wu2016-zt]. It will be noted that there is a sharp transition in decomposition rate at a depth of 0.3 m, reflecting the work of Frolking et al. (2001). As noted above, this value is widely accepted as a representative estimate of the depth dividing the acrotelm and catotelm. In reality, of course, this depth will vary among peatlands.

As only organic soil is considered in peatlands, the peat soil C is updated from the humification (C_{hum} , kg C / m² / day) and soil respiration from the oxic (R_o in kg C / m² / day) and anoxic (R_a in kg C / m² / day) components during the time step:

$$\frac{dC_{SOM}}{dt} = C_{hum} - R_o - R_a$$

C_{hum} is calculated as a PFT-dependent fraction of the decomposition rate. At the end of each time step, the peat depth (i.e. the depth of the organic soil) z_p is updated from the updated peat C mass (C_{SOM} in kg) by solving the quadratic equation

$$z_p = \frac{-k_{10} + \sqrt{k_{10}^2 + \frac{4k_9 C_{SOM}}{0.487}}}{2k_9}$$

The water table depth z_{wt} is deduced by searching for a soil layer below, which the soil is saturated and above which the soil moisture is at or below the retention capacity with respect to gravitational drainage. Within this soil layer j , z_{wt} is calculated as

$$z_{wt} = z_{b,j} - \Delta z \left[\frac{\theta_{l,j} + \theta_{i,j} - \theta_{ret,j}}{\theta_{p,j} - \theta_{ret,j}} \right]$$

where Δz is the thickness of soil layer (unit: m), θ_l and θ_i are the liquid and frozen water contents (unit: m³ / m³), θ_{ret} and θ_p are the water retention capacity and the porosity, and z_b (unit: m) is the bottom depth of the soil layer.

4.26.2 Function/Subroutine Documentation

4.26.2.1 subroutine, public peatlands_mod::hetres_peat (integer, intent(in) *il1*, integer, intent(in) *il2*, integer, dimension(ilg), intent(in) *ipeatland*, integer, dimension(ilg,ignd), intent(in) *isand*, real, dimension(ilg), intent(in) *litrmsmoss*, real, dimension(ilg), intent(in) *peatdep*, real, dimension(ilg), intent(in) *wtable*, real, dimension(ilg,ignd), intent(in) *tbar*, real, dimension(ilg,ignd), intent(in) *thliq*, real, dimension(ilg,ignd), intent(in) *thice*, real, dimension(ilg,ignd), intent(in) *thpor*, real, dimension(ilg,ignd), intent(in) *bi*, real, dimension(ilg,ignd), intent(in) *zbotw*, real, dimension(ilg,ignd), intent(in) *delzw*, real, dimension(ilg,ignd), intent(in) *psisat*, real, dimension(ilg), intent(out) *litresms*, real, dimension(ilg), intent(out) *socresp*, real, dimension(ilg), intent(out) *resoxic*, real, dimension(ilg), intent(out) *resanoxic*)

grid average peat soil heterotrophic respiration subroutine

Parameters

in	<i>ipeatland</i>	peatland flag, 0 = not peatland, 1 = bog, 2 = fen
in	<i>psisat</i>	saturated matrix potential in soil (m)
in	<i>wtable</i>	water table (m)
in	<i>tbar</i>	soil temperature (K)
out	<i>litresms</i>	moss litter respiration (\$ mol CO ₂ m ⁻² s ⁻¹)
out	<i>socresp</i>	soil C respiration (\$ mol CO ₂ m ⁻² s ⁻¹)
out	<i>resoxic</i>	respiration rate of the oxic compartment (\$ mol CO ₂ m ⁻² s ⁻¹)
out	<i>resanoxic</i>	respiration rate of the anoxic compartment (\$ mol CO ₂ m ⁻² s ⁻¹)

** calculate soil respiration from peat

find the effective water table depth and the layer index to divide the peat soil into two compartments

find the temperature in litter, oxic soil and anoxic soil in kelvin *lewtable* is the layer index of the water table layer, *lewtable* = 0 indicates WTD is above the ground surface. Set the oxic layer temperature to *dctmin* (minimum soil respiration temperature) when the entire soil is in the anoxic zone.

calculate the temperature multiplier (*ftsocres*) for oxic and anoxic soil compartments

find the heterotrophic respiration rate constant in the oxic and anoxic (unit in yr⁻¹), based on Fig.2b in Frolking 2001

Convert respiration rates from kg c/kg c.year to u-mol co₂/kgC/s

Find the carbon storage in oxic and anoxic compartments (C_{so}, C_{sa}) The water table depth delineates the oxic and anoxic compartments. functions (R**2 = 0.9999) determines the carbon content of each compartment from a peat bulk density profile based on unpulished data from P.J.H. Richard (described in fig. 1, Frolking et al.(2001) conversion of peat into carbon with 48.7% (Mer Bleue unpublished data, Moore)

Find the soil respiration rate in C_{so} and C_{sa} umol/m²/s. Moisture multiplier (0.025) indicates rate reduction in decomposition due to anoxia (Frolking et al. 2001), only applied to anoxic layer

**calcualte litter respiration of moss

first find the matrix potential of the soil layers

- real, dimension(:), allocatable [ustarbs](#)
- real, dimension(:), allocatable [tcsnow](#)
- real, dimension(:), allocatable [gsnow](#)
- real, dimension(:), allocatable [alirgat](#)

Diagnosed total near-infrared albedo of land surface [].

- real, dimension(:), allocatable [alvsgat](#)

Diagnosed total visible albedo of land surface [].

- real, dimension(:), allocatable [cdhgate](#)

Surface drag coefficient for heat [].

- real, dimension(:), allocatable [cdmgat](#)

Surface drag coefficient for momentum [].

- real, dimension(:), allocatable [drgat](#)

Surface drag coefficient under neutral stability [].

- real, dimension(:), allocatable [efgat](#)

Evaporation efficiency at ground surface [].

- real, dimension(:), allocatable [flgggat](#)

Diagnosed net longwave radiation at soil surface [Wm^{-2}].

- real, dimension(:), allocatable [flgsgat](#)

Diagnosed net longwave radiation at snow surface [Wm^{-2}].

- real, dimension(:), allocatable [flvggat](#)

Diagnosed net longwave radiation on vegetation canopy [Wm^{-2}].

- real, dimension(:), allocatable [fsgggat](#)

Diagnosed net shortwave radiation at soil surface [Wm^{-2}].

- real, dimension(:), allocatable [fsgsgat](#)

Diagnosed net shortwave radiation at snow surface [Wm^{-2}].

- real, dimension(:), allocatable [fsgvgat](#)

Diagnosed net shortwave radiation on vegetation canopy [Wm^{-2}].

- real, dimension(:), allocatable [fsnogat](#)

Diagnosed fractional snow coverage [].

- real, dimension(:), allocatable [gagat](#)

Diagnosed product of drag coefficient and wind speed over modelled area [ms^{-1}].

- real, dimension(:), allocatable [gtgat](#)

Diagnosed effective surface black-body temperature [K].

- real, dimension(:), allocatable [hblgat](#)

Height of the atmospheric boundary layer [m].

- real, dimension(:), allocatable [hevvgat](#)

Diagnosed latent heat flux on vegetation canopy [Wm^{-2}].

- real, dimension(:), allocatable [hevvgat](#)

Diagnosed latent heat flux at soil surface [Wm^{-2}].

- real, dimension(:), allocatable [hevsgat](#)

Diagnosed latent heat flux at snow surface [Wm^{-2}].

- real, dimension(:), allocatable [hfsgat](#)
Diagnosed total surface sensible heat flux over modelled area [$W m^{-2}$].
- real, dimension(:), allocatable [hfscgat](#)
Diagnosed sensible heat flux on vegetation canopy [$W m^{-2}$].
- real, dimension(:), allocatable [hfsggat](#)
Diagnosed sensible heat flux at soil surface [$W m^{-2}$].
- real, dimension(:), allocatable [hfssgat](#)
Diagnosed sensible heat flux at snow surface [$W m^{-2}$].
- real, dimension(:), allocatable [hmfcat](#)
Diagnosed energy associated with phase change of water on vegetation [$W m^{-2}$].
- real, dimension(:), allocatable [hmfngat](#)
Diagnosed energy associated with phase change of water in snow pack [$W m^{-2}$].
- real, dimension(:), allocatable [htccgat](#)
Diagnosed internal energy change of vegetation canopy due to conduction and/or change in mass [$W m^{-2}$].
- real, dimension(:), allocatable [htcsgat](#)
Diagnosed internal energy change of snow pack due to conduction and/or change in mass [$W m^{-2}$].
- real, dimension(:), allocatable [ilmogat](#)
Inverse of Monin-Obukhov roughness length (m^{-1}).
- real, dimension(:), allocatable [pfcgat](#)
Diagnosed frozen precipitation intercepted by vegetation [$kg m^{-2} s^{-1}$].
- real, dimension(:), allocatable [pclcgat](#)
Diagnosed liquid precipitation intercepted by vegetation [$kg m^{-2} s^{-1}$].
- real, dimension(:), allocatable [pcpggat](#)
Diagnosed precipitation incident on ground [$kg m^{-2} s^{-1}$].
- real, dimension(:), allocatable [pcpngat](#)
Diagnosed precipitation incident on snow pack [$kg m^{-2} s^{-1}$].
- real, dimension(:), allocatable [petgat](#)
Diagnosed potential evapotranspiration [$kg m^{-2} s^{-1}$].
- real, dimension(:), allocatable [qevpgat](#)
Diagnosed total surface latent heat flux over modelled area [$W m^{-2}$].
- real, dimension(:), allocatable [qfcgat](#)
Diagnosed vapour flux from frozen water on vegetation [$kg m^{-2} s^{-1}$].
- real, dimension(:), allocatable [qfcgat](#)
Diagnosed vapour flux from liquid water on vegetation [$kg m^{-2} s^{-1}$].
- real, dimension(:), allocatable [qfggat](#)
Diagnosed water vapour flux from ground [$kg m^{-2} s^{-1}$].
- real, dimension(:), allocatable [qfngat](#)
Diagnosed water vapour flux from snow pack [$kg m^{-2} s^{-1}$].
- real, dimension(:), allocatable [qfsgat](#)
Diagnosed total surface water vapour flux over modelled area [$kg m^{-2} s^{-1}$].
- real, dimension(:), allocatable [qfxgat](#)
Product of surface drag coefficient, wind speed and surface-air specific humidity difference [$m s^{-1}$].
- real, dimension(:), allocatable [qggat](#)
Diagnosed surface specific humidity [$kg kg^{-1}$].
- real, dimension(:), allocatable [rofgat](#)
Total runoff from soil [$kg m^{-2} s^{-1}$].
- real, dimension(:), allocatable [rofbgat](#)
Base flow from bottom of soil column [$kg m^{-2} s^{-1}$].
- real, dimension(:), allocatable [rofcgat](#)
Liquid/frozen water runoff from vegetation [$kg m^{-2} s^{-1}$].
- real, dimension(:), allocatable [rofngat](#)

- Liquid water runoff from snow pack $[kgm^{-2}s^{-1}]$.*

 - real, dimension(:), allocatable [rofogat](#)
- Overland flow from top of soil column $[kgm^{-2}s^{-1}]$.*

 - real, dimension(:), allocatable [rofsgat](#)
- Interflow from sides of soil column $[kgm^{-2}s^{-1}]$.*

 - real, dimension(:), allocatable [rovvgat](#)
- Diagnosed liquid/frozen water runoff from vegetation to ground surface $[kgm^{-2}s^{-1}]$.*

 - real, dimension(:), allocatable [sfcqgat](#)
- Diagnosed screen-level specific humidity $[kgkg^{-1}]$.*

 - real, dimension(:), allocatable [sfctgat](#)
- Diagnosed screen-level air temperature $[K]$.*

 - real, dimension(:), allocatable [sfcugat](#)
- Diagnosed anemometer-level zonal wind $[ms^{-1}]$.*

 - real, dimension(:), allocatable [sfvcgat](#)
- Diagnosed anemometer-level meridional wind $[ms^{-1}]$.*

 - real, dimension(:), allocatable [tfxgat](#)
- Product of surface drag coefficient, wind speed and surface-air temperature difference $[Kms^{-1}]$.*

 - real, dimension(:), allocatable [trobgat](#)
- Temperature of base flow from bottom of soil column $[K]$.*

 - real, dimension(:), allocatable [trofgat](#)
- Temperature of total runoff $[K]$.*

 - real, dimension(:), allocatable [troogat](#)
- Temperature of overland flow from top of soil column $[K]$.*

 - real, dimension(:), allocatable [trosgat](#)
- Temperature of interflow from sides of soil column $[K]$.*

 - real, dimension(:), allocatable [uegat](#)
- Friction velocity of air $[ms^{-1}]$.*

 - real, dimension(:), allocatable [wtabgat](#)
- Depth of water table in soil $[m]$.*

 - real, dimension(:), allocatable [wtrcgat](#)
- Diagnosed residual water transferred off the vegetation canopy $[kgm^{-2}s^{-1}]$.*

 - real, dimension(:), allocatable [wtrggat](#)
- Diagnosed residual water transferred into or out of the soil $[kgm^{-2}s^{-1}]$.*

 - real, dimension(:), allocatable [wtrsgat](#)
- Diagnosed residual water transferred into or out of the snow pack $[kgm^{-2}s^{-1}]$.*

 - real, dimension(:), allocatable [wtablegat](#)
- Depth of water table in soil $[m]$.*

5.8.1 Detailed Description

CTEM's variables monthly averaged (per pft)

The documentation for this type was generated from the following file:

- [src/ctem_statevars.f90](#)

5.9 ctem_statevars::ctem_switches Type Reference

switches for running the model, read from the joboptions file

Public Attributes

- logical [ctem_on](#)
True if this run includes CTEM.
- logical [cyclemet](#)
to cycle over only a fixed number of years (nummetcylrs) starting at a certain year (metcylrst) if cyclemet, then put transientCO2 = false and set an appropriate fixedCO2Conc, also if transientPOPD is true, it will choose the popn and luc data for year metcylrst and cycle on that.
- integer [metloop](#)
no. of times the .met file is to be read. this option is useful to see how ctem's c pools equilibrate when driven with same climate data over and over again.
- integer [trans_startyr](#)
the year you want the transient run to start (e.g. 1850). If you are not doing a transient run, set to a negative value (like -9999)
- integer [ncyear](#)
no. of years in the .met file.
- integer [spinfast](#)
set this to a higher number up to 10 to spin up soil carbon pool faster
- integer [nummetcylrs](#)
years of the climate file to spin up on repeatedly ignored if cyclemet is false
- integer [metcylrst](#)
climate year to start the spin up on ignored if cyclemet is false
- logical [transientco2](#)
use CO₂ time series, set to false if cyclemet is true
- character(180) [co2file](#)
Location of the netcdf file containing atmospheric CO2 values.
- integer [fixedyearco2](#)
set the year to use for atmospheric CO₂ if transientCO2 is false. (ppmv)
- logical [dofire](#)
boolean, if true allow fire, if false no fire.
- logical [met_rewound](#)
Remove FLAG.
- logical [reach_eof](#)
Remove FLAG.
- logical [pftcompetition](#)
logical boolean telling if competition between pfts is on or not
- logical [start_bare](#)
set this to true if competition is true, and if you wish to start from bare ground. if this is set to false, the ini and ctm file info will be used to set up the run. NOTE: This still keeps the crop fractions (while setting all pools to zero)
- logical [Induseon](#)
logical switch to run the land use change subroutine or not.
- character(180) [lucfile](#)
Location of the netcdf file containing land use change information.
- integer [fixedyearluc](#)
set the year to use for LUC
- logical [transientch4](#)
use CH₄ time series, set to false if cyclemet is true the CO₂ timeseries is in the same input file as the CO₂ one.

- character(180) [ch4file](#)
Location of the netcdf file containing atmospheric CH₄ values.
- integer [fixedyearch4](#)
set the year to use for atmospheric CH₄ if transientCH₄ is false. (ppmv)
- logical [transientpopd](#)
if set true use population density data to calculate fire extinguishing probability and probability of fire due to human causes
- character(180) [popdfile](#)
Location of the netcdf file containing population density values.
- integer [fixedyearpopd](#)
popd and luc year to cycle on when cyclemet is true, set to -9999 to cycle on metcylyrst for both popd and luc. if cyclemet is false this defaults to -9999, which will then cause the model to cycle on whatever is the first year in the popd and luc datasets
- character(180) [lghtfile](#)
Location of the netcdf file containing lightning density values.
- logical [inibioclim](#)
switch telling if bioclimatic parameters are being initialized from scratch (false) or being initialized from some spun up values(true).
- logical [leap](#)
set to true if all/some leap years in the .MET file have data for 366 days also accounts for leap years in .MET when cycling over meteorology (cyclemet)
- logical [dowetlands](#)
if true allow wetland methane emission
- logical [obswetf](#)
observed wetland fraction
- logical [transient_run](#)
- logical [use_netcdf](#)
If true all model inputs and outputs are handled via netcdfs.
- character(180) [met_file](#)
location of the netcdf meteorological dataset
- character(180) [init_file](#)
location of the netcdf initialization file
- character(180) [rs_file_to_overwrite](#)
location of the netcdf file that will be written for the restart file
- character(180) [runparams_file](#)
location of the namelist file containing the model parameters
- character(180) [comment](#)
Comment about the run that will be written to the output netcdfs.
- character(180) [output_directory](#)
Directory where the output netcdfs will be placed.
- character(180) [xmlfile](#)
location of the xml file that outlines the possible netcdf output files
- integer [jmosty](#)
Year to start writing out the monthly output files. If you want to write monthly outputs right from the start then put in a negative number (like -9999), if you never want to have monthly outputs put a large positive number (like 9999). This is given in the same timescale as IYEAR.
- logical [doperpftoutput](#)
Switch for making extra output files that are at the per PFT level.
- logical [dopertileoutput](#)
Switch for making extra output files that are at the per tile level.
- logical [domonthoutput](#)
Switch for making monthly output files (annual are always outputted)

- logical [dodayoutput](#)
Switch for making daily output files (annual are always outputted)
- logical [dohhoutput](#)
Switch for making half hourly output files (annual are always outputted)
- integer [idisp](#)
if idisp=0, vegetation displacement heights are ignored, because the atmospheric model considers these to be part of the "terrain". if idisp=1, vegetation displacement heights are calculated.
- integer [izref](#)
if izref=1, the bottom of the atmospheric model is taken to lie at the ground surface. if izref=2, the bottom of the atmospheric model is taken to lie at the local roughness height.
- integer [islfd](#)
if islfd=0, drcoef is called for surface stability corrections and the original gcm set of screen-level diagnostic calculations is done. if islfd=1, drcoef is called for surface stability corrections and sldiag is called for screen-level diagnostic calculations. if islfd=2, flxsurfz is called for surface stability corrections and diasurf is called for screen-level diagnostic calculations.
- integer [ipcp](#)
if ipcp=1, the rainfall-snowfall cutoff is taken to lie at 0 c. if ipcp=2, a linear partitioning of precipitation between rainfall and snowfall is done between 0 c and 2 c. if ipcp=3, rainfall and snowfall are partitioned according to a polynomial curve between 0 c and 6 c.
- integer [iwf](#)
if iwf=0, only overland flow and baseflow are modelled, and the ground surface slope is not modelled. if iwf=n (0<n<4), the watflood calculations of overland flow and interflow are performed; interflow is drawn from the top n soil layers.
- integer [itc](#)
itc, itcg and itg are switches to choose the iteration scheme to be used in calculating the canopy or ground surface temperature respectively. if the switch is set to 1, a bisection method is used; if to 2, the newton-raphson method is used.
- integer [itcg](#)
itc, itcg and itg are switches to choose the iteration scheme to be used in calculating the canopy or ground surface temperature respectively. if the switch is set to 1, a bisection method is used; if to 2, the newton-raphson method is used.
- integer [itg](#)
itc, itcg and itg are switches to choose the iteration scheme to be used in calculating the canopy or ground surface temperature respectively. if the switch is set to 1, a bisection method is used; if to 2, the newton-raphson method is used.
- integer [ipai](#)
if ipai, ihgt, ialc, ials and ialg are zero, the values of plant area index, vegetation height, canopy albedo, snow albedo and soil albedo respectively calculated by class are used. if any of these switches is set to 1, the value of the corresponding parameter calculated by class is overridden by a user-supplied input value.
- integer [ihgt](#)
if ipai, ihgt, ialc, ials and ialg are zero, the values of plant area index, vegetation height, canopy albedo, snow albedo and soil albedo respectively calculated by class are used. if any of these switches is set to 1, the value of the corresponding parameter calculated by class is overridden by a user-supplied input value.
- integer [ialc](#)
if ipai, ihgt, ialc, ials and ialg are zero, the values of plant area index, vegetation height, canopy albedo, snow albedo and soil albedo respectively calculated by class are used. if any of these switches is set to 1, the value of the corresponding parameter calculated by class is overridden by a user-supplied input value.
- integer [ials](#)
if ipai, ihgt, ialc, ials and ialg are zero, the values of plant area index, vegetation height, canopy albedo, snow albedo and soil albedo respectively calculated by class are used. if any of these switches is set to 1, the value of the corresponding parameter calculated by class is overridden by a user-supplied input value.
- integer [ialg](#)
if ipai, ihgt, ialc, ials and ialg are zero, the values of plant area index, vegetation height, canopy albedo, snow albedo and soil albedo respectively calculated by class are used. if any of these switches is set to 1, the value of the corresponding parameter calculated by class is overridden by a user-supplied input value.
- integer [jhhstd](#)

- day of the year to start writing the half-hourly output*
- integer [jhhendd](#)
 - day of the year to stop writing the half-hourly output*
- integer [jdstd](#)
 - day of the year to start writing the daily output*
- integer [jdenndd](#)
 - day of the year to stop writing the daily output*
- integer [jhhsty](#)
 - simulation year (iyear) to start writing the half-hourly output*
- integer [jhhendy](#)
 - simulation year (iyear) to stop writing the half-hourly output*
- integer [jdsty](#)
 - simulation year (iyear) to start writing the daily output*
- integer [jdeny](#)
 - simulation year (iyear) to stop writing the daily output*
- integer [isnoalb](#)
 - if isnoalb is set to 0, the original two-band snow albedo algorithms are used. if it is set to 1, the new four-band routines are used.*
- character(80) [titlec1](#)
 - Remove FLAG.*
- character(80) [titlec2](#)
 - Remove FLAG.*
- character(80) [titlec3](#)
 - Remove FLAG.*

5.9.1 Detailed Description

switches for running the model, read from the joboptions file

The documentation for this type was generated from the following file:

Public Attributes

- real, dimension(:,:), allocatable **ailcmin**
- real, dimension(:,:), allocatable **ailcmax**
- real, dimension(:,:), allocatable **dvdscan**
- real, dimension(:,:), allocatable **gleafmas**
green leaf mass for each of the 9 ctem pfts, kgc/m^2
- real, dimension(:,:), allocatable **bleafmas**
brown leaf mass for each of the 9 ctem pfts, kgc/m^2
- real, dimension(:,:), allocatable **stemmass**
stem mass for each of the 9 ctem pfts, kgc/m^2
- real, dimension(:,:), allocatable **rootmass**
root mass for each of the 9 ctem pfts, kgc/m^2
- real, dimension(:,:), allocatable **pstemmass**
stem mass from previous timestep, is value before fire. used by burntobare subroutine
- real, dimension(:,:), allocatable **pgleafmass**
root mass from previous timestep, is value before fire. used by burntobare subroutine
- real, dimension(:,:), allocatable **fcancmx**
max. fractional coverage of ctem's 9 pfts, but this can be modified by land-use change, and competition between pfts
- real, dimension(:), allocatable **gavglai**
grid averaged green leaf area index
- real, dimension(:), allocatable **lightng**
total lightning frequency, flashes/km2.year
- real, dimension(:), allocatable **tcanoaccgat_out**
- real, dimension(:,:), allocatable **zolnc**
lumped log of roughness length for class' 4 pfts
- real, dimension(:,:), allocatable **ailc**
lumped lai for class' 4 pfts
- real, dimension(:,:), allocatable **ailcg**
green lai for ctem's 9 pfts
- real, dimension(:,:), allocatable **ailcgs**
GREEN LAI FOR CANOPY OVER SNOW SUB-AREA.

- real, dimension(:,:), allocatable [fcancs](#)
FRACTION OF CANOPY OVER SNOW FOR CTEM's 9 PFTs.
- real, dimension(:,:), allocatable [fcanc](#)
FRACTIONAL COVERAGE OF 8 CARBON PFTs, CANOPY OVER GROUND.
- real, dimension(:), allocatable [co2conc](#)
ATMOS. CO2 CONC. IN PPM.
- real, dimension(:), allocatable **ch4conc**
- real, dimension(:,:), allocatable [co2i1cg](#)
INTERCELLULAR CO2 CONC FOR 8 PFTs FOR CANOPY OVER GROUND SUBAREA (Pa) - FOR SINGLE/SUNLIT LEAF.
- real, dimension(:,:), allocatable [co2i1cs](#)
SAME AS ABOVE BUT FOR SHADED LEAF (above being co2i1cg)
- real, dimension(:,:), allocatable [co2i2cg](#)
INTERCELLULAR CO2 CONC FOR 8 PFTs FOR CANOPY OVER SNOWSUBAREA (Pa) - FOR SINGLE/SUNLIT LEAF.
- real, dimension(:,:), allocatable [co2i2cs](#)
SAME AS ABOVE BUT FOR SHADED LEAF (above being co2i2cg)
- real, dimension(:,:), allocatable [ancsveg](#)
net photosynthetic rate for ctems 9 pfts for canopy over snow subarea
- real, dimension(:,:), allocatable [ancgveg](#)
net photosynthetic rate for ctems 9 pfts for canopy over ground subarea
- real, dimension(:,:), allocatable [rmlcsveg](#)
leaf respiration rate for ctems 9 pfts for canopy over snow subarea
- real, dimension(:,:), allocatable [rmlcgveg](#)
leaf respiration rate for ctems 9 pfts for canopy over ground subarea
- real, dimension(:,:), allocatable [slai](#)
storage/imaginary lai for phenology purposes
- real, dimension(:,:), allocatable [ailcb](#)
brown lai for ctem's 9 pfts. for now we assume only grasses can have brown lai
- real, dimension(:), allocatable **canres**
- real, dimension(:,:), allocatable [flhrloss](#)
fall or harvest loss for deciduous trees and crops, respectively, $\text{kgc}/\text{m}^2 \text{ yr}$
- real, dimension(:,:), allocatable [grwtheff](#)
growth efficiency. change in biomass per year per unit max. lai (kgc/m^2)/(m^2/m^2), for use in mortality subroutine
- real, dimension(:,:), allocatable [lystmms](#)
stem mass at the end of last year
- real, dimension(:,:), allocatable [lyrotmas](#)
root mass at the end of last year
- real, dimension(:,:), allocatable [tymaxlai](#)
this year's maximum lai
- real, dimension(:), allocatable [vgbiomas](#)
grid averaged vegetation biomass, kgc/m^2
- real, dimension(:), allocatable [gavgltms](#)
grid averaged litter mass, kgc/m^2
- real, dimension(:), allocatable [gavgscms](#)
grid averaged soil c mass, kgc/m^2
- real, dimension(:,:), allocatable [stmhrlos](#)
stem harvest loss for crops, kgc/m^2
- real, dimension(:,:,:), allocatable [rmatc](#)
fraction of roots for each of class' 4 pfts in each soil layer
- real, dimension(:,:,:), allocatable [rmatctem](#)

- fraction of roots for each of ctem's 9 pfts in each soil layer*
- real, dimension(:, :), allocatable **litrmass**
litter mass for each of the 9 ctem pfts + bare, kgC/m^2
- real, dimension(:, :), allocatable **soilcmass**
soil carbon mass for each of the 9 ctem pfts + bare, kgC/m^2
- real, dimension(:, :), allocatable **vgbiomas_veg**
vegetation biomass for each pft
- real, dimension(:, :), allocatable **emit_co2**
carbon dioxide
- real, dimension(:, :), allocatable **emit_co**
carbon monoxide
- real, dimension(:, :), allocatable **emit_ch4**
methane
- real, dimension(:, :), allocatable **emit_nmhc**
non-methane hydrocarbons
- real, dimension(:, :), allocatable **emit_h2**
hydrogen gas
- real, dimension(:, :), allocatable **emit_nox**
nitrogen oxides
- real, dimension(:, :), allocatable **emit_n2o**
nitrous oxide
- real, dimension(:, :), allocatable **emit_pm25**
particulate matter less than 2.5 μm in diameter
- real, dimension(:, :), allocatable **emit_tpm**
total particulate matter
- real, dimension(:, :), allocatable **emit_tc**
total carbon
- real, dimension(:, :), allocatable **emit_oc**
organic carbon
- real, dimension(:, :), allocatable **emit_bc**
black carbon
- real, dimension(:, :), allocatable **burnfrac**
areal fraction burned due to fire for every grid cell (%)
- real, dimension(:, :), allocatable **burnveg**
per PFT fraction burned of that PFT's area
- real, dimension(:, :), allocatable **smfuncveg**
- real, dimension(:), allocatable **popdin**
population density (people / km^2)
- real, dimension(:, :), allocatable **bterm**
biomass term for fire probabiltiy calc
- real, dimension(:), allocatable **lterm**
lightning term for fire probabiltiy calc
- real, dimension(:, :), allocatable **mterm**
moisture term for fire probabiltiy calc
- real, dimension(:), allocatable **extnprob**
fire extinguishing probability
- real, dimension(:), allocatable **prbfrhuc**
probability of fire due to human causes
- real, dimension(:, :), allocatable **mlightng**
- real, dimension(:), allocatable **dayl_max**
maximum daylength for that location (hours)

- real, dimension(:), allocatable [dayl](#)
daylength for that location (hours)
- real, dimension(:, :), allocatable [bmasveg](#)
total (gleaf + stem + root) biomass for each ctem pft, kgC/m²
- real, dimension(:, :), allocatable [cmasvegc](#)
total canopy mass for each of the 4 class pfts. recall that class requires canopy mass as an input, and this is now provided by ctem. kg/m².
- real, dimension(:, :), allocatable [veghght](#)
vegetation height (meters)
- real, dimension(:, :), allocatable [rootdpth](#)
99% soil rooting depth (meters) both vegght & rootdpth can be used as diagnostics to see how vegetation grows above and below ground, respectively
- real, dimension(:), allocatable [rml](#)
leaf maintenance respiration (u-mol co2/m2.sec)
- real, dimension(:), allocatable [rms](#)
stem maintenance respiration (u-mol co2/m2.sec)
- real, dimension(:, :), allocatable [tlrleaf](#)
total leaf litter fall rate (u-mol co2/m2.sec)
- real, dimension(:, :), allocatable [tlrstem](#)
total stem litter fall rate (u-mol co2/m2.sec)
- real, dimension(:, :), allocatable [tlrroot](#)
total root litter fall rate (u-mol co2/m2.sec)
- real, dimension(:, :), allocatable [leafltr](#)
leaf litter fall rate (u-mol co2/m2.sec). this leaf litter does not include litter generated due to mortality/fire
- real, dimension(:, :), allocatable [roottemp](#)
root temperature, k
- real, dimension(:, :), allocatable [afrleaf](#)
allocation fraction for leaves
- real, dimension(:, :), allocatable [afrstem](#)
allocation fraction for stem
- real, dimension(:, :), allocatable [afrroot](#)
allocation fraction for root
- real, dimension(:, :), allocatable [wtstatus](#)
soil water status used for calculating allocation fractions
- real, dimension(:, :), allocatable [ltstatus](#)
light status used for calculating allocation fractions
- real, dimension(:), allocatable [rmr](#)
root maintenance respiration (u-mol co2/m2.sec)
- real, dimension(:, :), allocatable [slopefrac](#)
prescribed fraction of wetlands based on slope only(0.025, 0.05, 0.1, 0.15, 0.20, 0.25, 0.3 and 0.35 percent slope thresholds)
- real, dimension(:), allocatable [wetfrac_pres](#)
- real, dimension(:, :), allocatable [wetfrac_mon](#)
- real, dimension(:), allocatable [ch4wet1](#)
methane flux from wetlands calculated using hetrores in umol ch4/m2.s
- real, dimension(:), allocatable [ch4wet2](#)
methane flux from wetlands calculated using npp in umol ch4/m2.s
- real, dimension(:), allocatable [wetfdyn](#)
dynamic wetland fraction
- real, dimension(:), allocatable [ch4dyn1](#)
methane flux from wetlands calculated using hetrores and wetfdyn, in umol ch4/m2.s

- real, dimension(:), allocatable [ch4dyn2](#)
methane flux from wetlands calculated using npp and wetfdyn, in umol ch4/m2.s
- real, dimension(:), allocatable [ch4_soils](#)
Methane uptake into the soil column (\$mg CH_4 m^{-2} s^{-1}\$)
- real, dimension(:), allocatable [lucemcom](#)
land use change (luc) related combustion emission losses, u-mol co2/m2.sec
- real, dimension(:), allocatable [lucltrin](#)
luc related inputs to litter pool, u-mol co2/m2.sec
- real, dimension(:), allocatable [lucsocin](#)
luc related inputs to soil c pool, u-mol co2/m2.sec
- real, dimension(:), allocatable [npp](#)
net primary productivity
- real, dimension(:), allocatable [nep](#)
net ecosystem productivity
- real, dimension(:), allocatable [nbp](#)
net biome productivity
- real, dimension(:), allocatable [gpp](#)
gross primary productivity
- real, dimension(:), allocatable [hetrores](#)
heterotrophic respiration
- real, dimension(:), allocatable [autores](#)
autotrophic respiration
- real, dimension(:), allocatable [soilcresp](#)
- real, dimension(:), allocatable [rm](#)
maintenance respiration
- real, dimension(:), allocatable [rg](#)
growth respiration
- real, dimension(:), allocatable [litrres](#)
litter respiration
- real, dimension(:), allocatable [socres](#)
soil carbon respiration
- real, dimension(:), allocatable [dstcemls](#)
carbon emission losses due to disturbance, mainly fire
- real, dimension(:), allocatable [litrfall](#)
total litter fall (from leaves, stem, and root) due to all causes (mortality, turnover, and disturbance)
- real, dimension(:), allocatable [humiftrs](#)
transfer of humidified litter from litter to soil c pool
- real, dimension(:, :), allocatable [gppveg](#)
gross primary productivity for each pft
- real, dimension(:, :), allocatable [nepveg](#)
net ecosystem productivity for bare fraction expnbaln(i)=0.0 amount of c related to spatial expansion Not used JM Jun 2014 OR net ecosystem productivity for each pft
- integer, dimension(:), allocatable [ipeatland](#)
Peatland flag: 0 = not a peatland, 1 = bog, 2 = fen.
- real, dimension(:), allocatable [anmoss](#)
net photosynthetic rate of moss (\$ mol CO2 m^{-2} s^{-1}\$)
- real, dimension(:), allocatable [rmlmoss](#)
maintenance respiration rate of moss (\$ mol CO2 m^{-2} s^{-1}\$)
- real, dimension(:), allocatable [gppmoss](#)
gross primaray production of moss (\$ mol CO2 m^{-2} s^{-1}\$)
- real, dimension(:), allocatable [nppmoss](#)

- net primary production of moss (\$ mol CO₂ m⁻² s⁻¹)*

 - real, dimension(:), allocatable [armoss](#)
- autotrophic respiration of moss (\$ mol CO₂ m⁻² s⁻¹)*

 - real, dimension(:), allocatable [litrmsmoss](#)
- moss litter mass, kgC/m²*

 - real, dimension(:), allocatable [cmossmas](#)
- C in moss biomass, kgC/m².*

 - real, dimension(:), allocatable [dmoss](#)
- depth of living moss (m)*

 - real, dimension(:), allocatable [pdd](#)
- peatland degree days above 0 deg C.*

 - real, dimension(:), allocatable [ancsmoss](#)
- moss net photosynthesis in canopy snow subarea (\$ mol CO₂ m⁻² s⁻¹)*

 - real, dimension(:), allocatable [angsmoss](#)
- moss net photosynthesis in snow ground subarea (\$ mol CO₂ m⁻² s⁻¹)*

 - real, dimension(:), allocatable [ancmoss](#)
- moss net photosynthesis in canopy ground subarea (\$ mol CO₂ m⁻² s⁻¹)*

 - real, dimension(:), allocatable [angmoss](#)
- moss net photosynthesis in bare ground subarea (\$ mol CO₂ m⁻² s⁻¹)*

 - real, dimension(:), allocatable [rmlcsmoss](#)
- moss maintenance respiration in canopy snow subarea (\$ mol CO₂ m⁻² s⁻¹)*

 - real, dimension(:), allocatable [rmlgsmoss](#)
- moss maintenance respiration in ground snow subarea (\$ mol CO₂ m⁻² s⁻¹)*

 - real, dimension(:), allocatable [rmlcmoss](#)
- moss maintenance respiration in canopy ground subarea (\$ mol CO₂ m⁻² s⁻¹)*

 - real, dimension(:), allocatable [rmlgmoss](#)
- moss maintenance respiration in bare ground subarea (\$ mol CO₂ m⁻² s⁻¹)*

 - real, dimension(:), allocatable [nbpveg](#)
- net biome productivity for bare fraction OR net biome productivity for each pft*

 - real, dimension(:,:), allocatable [nppveg](#)
- npp for individual pfts, u-mol co2/m2.sec*

 - real, dimension(:,:), allocatable [hettoresveg](#)
 - real, dimension(:,:), allocatable [autoresveg](#)
 - real, dimension(:,:), allocatable [litresveg](#)
 - real, dimension(:,:), allocatable [soilcresveg](#)
 - real, dimension(:,:), allocatable [rmlvegacc](#)
 - real, dimension(:,:), allocatable [rmsveg](#)
- stem maintenance resp. rate for each pft*

 - real, dimension(:,:), allocatable [rmrveg](#)
- root maintenance resp. rate for each pft*

 - real, dimension(:,:), allocatable [rgveg](#)
- growth resp. rate for each pft*

 - real, dimension(:,:), allocatable [litrfallveg](#)
- litter fall in kgC/m² for each pft*

 - real, dimension(:,:), allocatable [humiftrsvveg](#)
- root death as crops are harvested, kgC/m²*

 - real, dimension(:,:), allocatable [pfcancmx](#)
- previous year's fractional coverages of pfts*

 - real, dimension(:,:), allocatable [nfcancmx](#)
- next year's fractional coverages of pfts*

- real, dimension(:,:), allocatable **alvsctm**
- real, dimension(:,:), allocatable **paic**
plant area index for class' 4 pfts. this is the sum of leaf area index and stem area index.
- real, dimension(:,:), allocatable **slaic**
storage lai. this will be used as min. lai that class sees so that it doesn't blow up in its stomatal conductance calculations.
- real, dimension(:,:), allocatable **alirctm**
- real, dimension(:), allocatable **cfluxcg**
- real, dimension(:), allocatable **cfluxcs**
- real, dimension(:), allocatable **dstcemls3**
carbon emission losses due to disturbance (fire at present) from litter pool
- real, dimension(:,:), allocatable **anveg**
net photosynthesis rate for each pft
- real, dimension(:,:), allocatable **rmlveg**
leaf maintenance resp. rate for each pft
- real, dimension(:), allocatable **twarmm**
temperature of the warmest month (c)
- real, dimension(:), allocatable **tcoldm**
temperature of the coldest month (c)
- real, dimension(:), allocatable **gdd5**
growing degree days above 5 c
- real, dimension(:), allocatable **aridity**
aridity index, ratio of potential evaporation to precipitation
- real, dimension(:), allocatable **srplsmon**
number of months in a year with surplus water i.e. precipitation more than potential evaporation
- real, dimension(:), allocatable **defctmon**
number of months in a year with water deficit i.e. precipitation less than potential evaporation
- real, dimension(:), allocatable **anndefct**
annual water deficit (mm)
- real, dimension(:), allocatable **annsrpls**
annual water surplus (mm)
- real, dimension(:), allocatable **annpcp**
annual precipitation (mm)
- real, dimension(:), allocatable **dry_season_length**
length of dry season (months)
- real, dimension(:), allocatable **tcurm**
temperature of the current month (c)
- real, dimension(:), allocatable **srpcuryr**
water surplus for the current year
- real, dimension(:), allocatable **dftcuryr**
water deficit for the current year
- real, dimension(:,:), allocatable **tmonth**
monthly temperatures
- real, dimension(:), allocatable **anpcpcur**
annual precipitation for current year (mm)
- real, dimension(:), allocatable **anpecur**
annual potential evaporation for current year (mm)
- real, dimension(:), allocatable **gdd5cur**
growing degree days above 5 c for current year
- real, dimension(:), allocatable **surmncur**
number of months with surplus water for current year

- real, dimension(:), allocatable [defmncur](#)
number of months with water deficit for current year
- real, dimension(:), allocatable [srplscur](#)
water surplus for the current month
- real, dimension(:), allocatable [defctcur](#)
water deficit for the current month
- real, dimension(:, :), allocatable [geremort](#)
growth efficiency related mortality (1/day)
- real, dimension(:, :), allocatable [intrmort](#)
intrinsic (age related) mortality (1/day)
- real, dimension(:, :), allocatable [lambda](#)
Used to determine the colonization rate.
- real, dimension(:, :), allocatable [cc](#)
colonization rate & mortality rate
- real, dimension(:, :), allocatable [mm](#)
colonization rate & mortality rate
- logical, dimension(:, :), allocatable [pftexist](#)
logical array indicating pfts exist (t) or not (f)
- integer, dimension(:, :), allocatable [colddays](#)
cold days counter for tracking days below a certain temperature threshold for ndl dcd and crop pfts.
- integer, dimension(:, :), allocatable [lfstatus](#)
leaf phenology status
- integer, dimension(:, :), allocatable [pandays](#)
days with positive net photosynthesis (an) for use in the phenology subroutine
- real, dimension(:), allocatable [grclarea](#)
area of the grid cell, km^2
- integer, dimension(:), allocatable [stdaln](#)
an integer telling if ctem is operated within gcm (=0) or in stand alone mode (=1). this is used for fire purposes. see comments just above where disturb subroutine is called.
- integer, dimension(:), allocatable [altotcount_ctm](#)
- real, dimension(:, :), allocatable [todfrac](#)
- real, dimension(:, :), allocatable [barf](#)
- real, dimension(:), allocatable [fsinacc_gat](#)
- real, dimension(:), allocatable [flutacc_gat](#)
- real, dimension(:), allocatable [flinacc_gat](#)
- real, dimension(:), allocatable [alswacc_gat](#)
- real, dimension(:), allocatable [allwacc_gat](#)
- real, dimension(:), allocatable [pregacc_gat](#)
- real, dimension(:), allocatable [altotacc_gat](#)
- real, dimension(:), allocatable [netrad_gat](#)
- real, dimension(:), allocatable [preacc_gat](#)
- real, dimension(:), allocatable [sdepgat](#)
- real, dimension(:, :), allocatable [rgmgat](#)
- real, dimension(:, :), allocatable [sandgat](#)
- real, dimension(:, :), allocatable [claygat](#)
- real, dimension(:, :), allocatable [orgmgat](#)
- real, dimension(:), allocatable [xdiffusgat](#)

5.17.1 Detailed Description

CTEM's 'gat' vars.

The documentation for this type was generated from the following file:

- [src/ctem_statevars.f90](#)

5.18 ctem_statevars::veg_rot Type Reference

CTEM's 'rot' vars.

Public Attributes

- logical, dimension(:,:,:), allocatable [pftexist](#)
logical array indicating pfts exist (t) or not (f)
- integer, dimension(:,:,:), allocatable [lfstatus](#)
leaf phenology status
- integer, dimension(:,:,:), allocatable [pandays](#)
days with positive net photosynthesis (an) for use in the phenology subroutine
- real, dimension(:,:,:), allocatable [ailcmin](#)
- real, dimension(:,:,:), allocatable [ailcmax](#)
- real, dimension(:,:,:), allocatable [dvdfcan](#)
- real, dimension(:,:,:), allocatable [gleafmas](#)
green leaf mass for each of the 9 ctem pfts, kgc/m^2
- real, dimension(:,:,:), allocatable [bleafmas](#)
brown leaf mass for each of the 9 ctem pfts, kgc/m^2
- real, dimension(:,:,:), allocatable [stemmass](#)
stem mass for each of the 9 ctem pfts, kgc/m^2
- real, dimension(:,:,:), allocatable [rootmass](#)
root mass for each of the 9 ctem pfts, kgc/m^2
- real, dimension(:,:,:), allocatable [pstemmass](#)
stem mass from previous timestep, is value before fire. used by burntobare subroutine
- real, dimension(:,:,:), allocatable [pgleafmass](#)
root mass from previous timestep, is value before fire. used by burntobare subroutine
- real, dimension(:,:,:), allocatable [fcancmx](#)
max. fractional coverage of ctem's 9 pfts, but this can be modified by land-use change, and competition between pfts
- real, dimension(:,:,:), allocatable [ailcg](#)
green lai for ctem's 9 pfts
- real, dimension(:,:,:), allocatable [ailcgs](#)
GREEN LAI FOR CANOPY OVER SNOW SUB-AREA.
- real, dimension(:,:,:), allocatable [fcancs](#)
FRACTION OF CANOPY OVER SNOW FOR CTEM's 9 PFTs.
- real, dimension(:,:,:), allocatable [fcanc](#)
FRACTIONAL COVERAGE OF 8 CARBON PFTs, CANOPY OVER SNOW.
- real, dimension(:,:,:), allocatable [co2i1cg](#)
INTERCELLULAR CO2 CONC FOR 8 PFTs FOR CANOPY OVER GROUND SUBAREA (Pa) - FOR SINGLE/SU↔NLIT LEAF.
- real, dimension(:,:,:), allocatable [co2i1cs](#)
SAME AS ABOVE BUT FOR SHADED LEAF (above being co2i1cg)
- real, dimension(:,:,:), allocatable [co2i2cg](#)

INTERCELLULAR CO2 CONC FOR 8 PFTs FOR CANOPY OVER SNOWSUBAREA (Pa) - FOR SINGLE/SUNLIT LEAF.

- real, dimension(:, :, :), allocatable [co2i2cs](#)
SAME AS ABOVE BUT FOR SHADED LEAF (above being co2i2cg)
- real, dimension(:, :, :), allocatable [ancsveg](#)
net photosynthetic rate for ctems 9 pfts for canopy over snow subarea
- real, dimension(:, :, :), allocatable [ancgveg](#)
net photosynthetic rate for ctems 9 pfts for canopy over ground subarea
- real, dimension(:, :, :), allocatable [rmlcsveg](#)
leaf respiration rate for ctems 9 pfts for canopy over snow subarea
- real, dimension(:, :, :), allocatable [rmlcgveg](#)
leaf respiration rate for ctems 9 pfts for canopy over ground subarea
- real, dimension(:, :, :), allocatable [slai](#)
storage/imaginary lai for phenology purposes
- real, dimension(:, :, :), allocatable [ailcb](#)
brown lai for ctem's 9 pfts. for now we assume only grasses can have brown lai
- real, dimension(:, :, :), allocatable [flhrloss](#)
fall or harvest loss for deciduous trees and crops, respectively, kgc/m^2 il1
- real, dimension(:, :, :), allocatable [grwtheff](#)
growth efficiency. change in biomass per year per unit max. lai (kgc/m^2)/(m^2/m^2), for use in mortality subroutine
- real, dimension(:, :, :), allocatable [lystmmas](#)
stem mass at the end of last year
- real, dimension(:, :, :), allocatable [lyrotmas](#)
root mass at the end of last year
- real, dimension(:, :, :), allocatable [tymaxlai](#)
this year's maximum lai
- real, dimension(:, :, :), allocatable [stmhrlos](#)
stem harvest loss for crops, kgc/m^2
- real, dimension(:, :, :), allocatable [vgbiomas_veg](#)
vegetation biomass for each pft
- real, dimension(:, :, :), allocatable [emit_co2](#)
carbon dioxide
- real, dimension(:, :, :), allocatable [emit_co](#)
carbon monoxide
- real, dimension(:, :, :), allocatable [emit_ch4](#)
methane
- real, dimension(:, :, :), allocatable [emit_nmhc](#)
non-methane hydrocarbons
- real, dimension(:, :, :), allocatable [emit_h2](#)
hydrogen gas
- real, dimension(:, :, :), allocatable [emit_nox](#)
nitrogen oxides
- real, dimension(:, :, :), allocatable [emit_n2o](#)
nitrous oxide
- real, dimension(:, :, :), allocatable [emit_pm25](#)
particulate matter less than 2.5 um in diameter
- real, dimension(:, :, :), allocatable [emit_tpm](#)
total particulate matter
- real, dimension(:, :, :), allocatable [emit_tc](#)
total carbon
- real, dimension(:, :, :), allocatable [emit_oc](#)

- organic carbon*
- real, dimension(:, :, :), allocatable [emit_bc](#)
- black carbon*
- real, dimension(:, :, :), allocatable [burnveg](#)
- per PFT fraction burned of that PFT's area*
- real, dimension(:, :, :), allocatable [smfuncveg](#)
- real, dimension(:, :, :), allocatable [bterm](#)
- biomass term for fire probability calc*
- real, dimension(:, :, :), allocatable [mterm](#)
- moisture term for fire probability calc*
- real, dimension(:, :, :), allocatable [bmasveg](#)
- total (leaf + stem + root) biomass for each ctem pft, kgC/m²*
- real, dimension(:, :, :), allocatable [vegght](#)
- vegetation height (meters)*
- real, dimension(:, :, :), allocatable [rootdpth](#)
- 99% soil rooting depth (meters) both vegght & rootdpth can be used as diagnostics to see how vegetation grows above and below ground, respectively*
- real, dimension(:, :, :), allocatable [ttrleaf](#)

Canadian Terrestrial Ecosystem Model (CTEM) Allocation Subroutine.

Functions/Subroutines

- subroutine [allocate](#) (lfstatus,thliq,ailcg,ailcb,il1,il2,sand,clay,rmatctem, gleafmas, stemmass, rootmass,sort, nol2pfts, fcancmx, isand,

6.1.1 Detailed Description

Canadian Terrestrial Ecosystem Model (CTEM) Allocation Subroutine.

Positive NPP is allocated daily to the leaf, stem and root components, which generally causes their respective biomass to increase, although the biomass may also decrease depending on the autotrophic respiration flux of a component. Negative NPP generally causes net carbon loss from the components. While CTEM offers the ability to use both specified constant or dynamically calculated allocation fractions for leaves, stems and roots, in practice the dynamic allocation fractions are primarily used. The formulation used in CTEM v. 2.0 differs from that for CTEM v. 1.0 as described in **[Arora2005-6b1]** only in the parameter values.

The dynamic allocation to the live plant tissues is based on the light, water and leaf phenological status of vegetation. The preferential allocation of carbon to the different tissue pools is based on three assumptions: (i) if soil moisture is limiting, carbon should be preferentially allocated to roots for greater access to water, (ii) if LAI is low, carbon should be allocated to leaves for enhanced photosynthesis and finally (iii) carbon is allocated to the stem to increase vegetation height and lateral spread of vegetation when the increase in LAI results in a decrease in light penetration.

The vegetation water status, W , is determined as a linear scalar quantity that varies between 0 and 1 for each PFT and calculated by weighting the degree of soil saturation (ϕ_i , Eq. [phitheta](#)) with the fraction of roots in each soil layer

$$W = \phi_{root} = \sum_{i=1}^g \phi_i(\theta_i)r_i.$$

The light status, L , is parametrized as a function of LAI and nitrogen extinction coefficient, k_n (PFT-dependent; see also [ctem_params.f90](#)), as

$$L = \{ \exp(-k_n LAI), \quad treesandcrops \max\left(0, 1 - \frac{LAI}{4.5}\right), \quad grasses.$$

For PFTs with a stem component (i.e. tree and crop PFTs), the fractions of positive NPP allocated to stem (a_{fS}),

leaf (a_{fL}) and root (a_{fR}) components are calculated as

$$a_{fS} = \frac{\epsilon_S + \omega_a(1 - L)}{1 + \omega_a(2 - L - W)}$$

$$a_{fR} = \frac{\epsilon_R + \omega_a(1 - W)}{1 + \omega_a(2 - L - W)},$$

$$a_{fL} = \frac{\epsilon_L}{1 + \omega_a(2 - L - W)} = 1 - a_{fS} - a_{fR}.$$

The base allocation fractions for each component (leaves – ϵ_L , stem – ϵ_S , and roots – ϵ_R) are PFT-dependent (see also [ctem_params.f90](#)) and sum to 1, i.e. $\epsilon_L + \epsilon_S + \epsilon_R = 1$. The parameter ω_a , which varies by PFT (see also [ctem_params.f90](#)), determines the sensitivity of the allocation scheme to changes in W and L . Larger values of ω_a yield higher sensitivity to changes in L and W .

Grasses do not have a stem component (i.e. $a_{fS} = 0$) and the allocation fractions for leaf and root components are given by

$$a_{fL} = \frac{\epsilon_L + \omega_a L}{1 + \omega_a(1 + L - W)}, a_{fR} = \frac{\epsilon_R + \omega_a(1 - W)}{1 + \omega_a(1 + L - W)}.$$

The above equations ensure that the allocation fractions add up to one ($a_{fL} + a_{fR} + a_{fS} = 1$).

The dynamic allocation fractions are superseded under three conditions. First, during the leaf onset for crops and deciduous trees, all carbon must be allocated to leaves ($a_{fL} = 1$, $a_{fS} = a_{fR} = 0$). Second, the proportion of stem plus root biomasses to leaf biomass must satisfy the relationship:

$$C_S + C_R = \eta C_L^\kappa,$$

where C_S , C_R and C_L are the carbon in the stem, root and leaves, respectively. The parameter η is PFT-specific (see also [ctem_params.f90](#)) and parameter κ has a value of 1.6 for trees and crops and 1.2 for grasses. Both parameters are based on the Frankfurt Biosphere Model (FBM) [Ludeke1994-px]. This constraint (Eq. propwoody) is based on the physical requirement of sufficient stem and root tissues to support a given leaf biomass. As grasses have no stem component, Eq. (propwoody) determines their root to shoot ratio (i.e. the ratio of belowground to aboveground biomass). The final condition ensures that a minimum realistic root to shoot ratio is maintained for all PFTs (lr_{min} , see also [ctem_params.f90](#)). Root mass is required for nutrient and water uptake and support for the aboveground biomass. If the minimum root to shoot ratio is not being maintained, carbon is allocated preferentially to roots.

6.1.2 Function/Subroutine Documentation

6.1.2.1 subroutine `allocate` (integer, dimension(ilg,icc) *lfstatus*, real, dimension(ilg,ignd) *thliq*, real, dimension(ilg,icc) *ailcg*, real, dimension(ilg,icc) *ailcb*, integer *il1*, integer *il2*, real, dimension(ilg,ignd) *sand*, real, dimension(ilg,ignd) *clay*, real, dimension(ilg,icc,ignd) *rmatctem*, real, dimension(ilg,icc) *gleafmas*, real, dimension(ilg,icc) *stemmass*, real, dimension(ilg,icc) *rootmass*, integer, dimension(icc) *sort*, integer, dimension(ican) *no12pfts*, real, dimension(ilg,icc) *fcancmx*, integer, dimension(ilg,ignd) *isand*)

Parameters

<i>il1</i>	input: il1=1
<i>il2</i>	input: il2=ilg
<i>lfstatus</i>	input: leaf status. an integer indicating if leaves are in "max. growth", "normal growth", "fall/harvest", or "no leaves" mode. see phenolgy subroutine for more details.

<i>sort</i>	input: index for correspondence between 9 pfts and the 12 values in parameters vectors
<i>nol2pfts</i>	input: number of level 2 ctem pfts
<i>ailcg</i>	input: green or live leaf area index
<i>ailcb</i>	input: brown or dead leaf area index
<i>thliq</i>	input: liquid soil moisture content in 3 soil layers
<i>rootmass</i>	input: root mass for each of the 9 ctem pfts, kg c/m2
<i>rmatctem</i>	input: fraction of roots in each soil layer for each pft
<i>gleafmas</i>	input: green or live leaf mass in kg c/m2, for the 9 pfts
<i>stemmass</i>	input: stem mass for each of the 9 ctem pfts, kg c/m2
<i>sand</i>	input: percentage sand
<i>clay</i>	input: percentage clay
<i>fcancmx</i>	input: max. fractional coverage of ctem's 9 pfts, but this can be modified by land-use change, and competition between pfts

Calculate liquid soil moisture content, and wilting and field capacity soil moisture contents averaged over the root zone. note that while the soil moisture content is same under the entire gcm grid cell, soil moisture averaged over the rooting depth is different for each pft because of different fraction of roots present in each soil layer.

Using liquid soil moisture content together with wilting and field capacity soil moisture contents averaged over the root zone, find soil water status.

Calculate light status as a function of lai and light extinction parameter. for now set nitrogen status equal to 1, which means nitrogen is non-limiting.

allocation to roots is determined by min. of water and nitrogen status

now that we know water, light, and nitrogen status we can find allocation fractions for leaves, stem, and root components. note that allocation formulae for grasses are different from those for trees and crops, since there is no stem component in grasses.

if using constant allocation factors then replace the dynamically calculated allocation fractions.

make sure allocation fractions add to one

the allocation fractions calculated above are overridden by two rules.

rule 1 which states that at the time of leaf onset which corresponds to leaf status equal to 1, more c is allocated to leaves so that they can grow asap. in addition when leaf status is "fall/harvest" then nothing is allocated to leaves.

for grasses we use the usual allocation even at leaf onset

rule 2 overrides rule 1 above and makes sure that we do not allow the amount of leaves on trees and crops (i.e. pfts 1 to 7) to exceed an amount such that the remaining woody biomass cannot support. if this happens, allocation to leaves is reduced and most npp is allocated to stem and roots, in a proportion based on calculated afrstem and afrroot. for grasses this rule essentially constrains the root:shoot ratio, meaning that the model grasses can't have lots of leaves without having a reasonable amount of roots.

make sure that root:shoot ratio is at least equal to rtsrmin. if not allocate more to root and decrease allocation to stem.

finally check if all allocation fractions are positive and check again they all add to one.

6.2 src/APREP.f File Reference

Purpose: Calculate various land surface parameters.

Functions/Subroutines

- subroutine [aprep](#) (FC, FG, FCS, FGS, PAICAN, PAICNS, FSVF, FSVFS, FRAIN, FSNOWC, FRAICS, FRAICNS, RAICAN, RAICNS, SNOCAN, SNOCONS, DISP, DISPS, ZOMLNC, ZOMLCS, ZOELNC, ZOELCS, ZOMLNG, ZOMLNS, ZOELNG, ZOELNS, CHCAP, CHCAPS, CMASSC, CMASCS, CWLCAP, CWFCAP, CWLCPS, CWFCPS, RBCOEF, ZPLIMC, ZPLIMG, ZPLMCS, ZPLMGS, HTCC, HTCS, HTC, FROOT, FR←

OOTS, WTRC, WTRS, WTRG, CMAI, PAI, PAIS, AIL, FCAN, FCANS, PSIGND, FCANMX, ZOLN, PAIMAX, PAIMIN, CWGTMX, ZRTMAX, PAIDAT, HGTDAT, THLIQ, THICE, TBAR, RCAN, SNCAN, TCAN, GROWTH, ZSNOW, TSNOW, FSNOW, RHOSNO, SNO, ZOORO, ZBLEND, ZPLMG0, ZPLMS0, TA, RHOAIR, RADJ, DLON, RHOSNI, DELZ, DELZW, ZBOTW, THPOR, THLMIN, PSISAT, BI, PSIWL, HCPS, ISAND, ILG, IL1, IL2, JL, IC, ICP1, IG, IDAY, IDISP, IZREF, IWF, IPAI, IHGT, RMAT, H, HS, CWCPAV, GROWA, GROWN, GROWB, RRESID, SRESID, FRTOT, FRTOTS, FCANCMX, ICTEM, ctem_on, RMATC, AILC, PAIC, AILCG, L2MAX, NOL2PFTS, AILCGS, FCANCS, FCANC, ZOLNC, CMASVEGC, SLAIC, ipeatland)

This subroutine is hard-coded to handle the standard four vegetation categories recognized by CLASS (needleleaf trees, broadleaf trees, crops and grass), so a call to abort is performed if the number of vegetation classes, IC, is not equal to 4. A set of diagnostic and accumulator arrays is then initialized to zero, and the liquid water suction in the soil is set to an arbitrarily high value.

6.2.1 Detailed Description

Purpose: Calculate various land surface parameters.

6.2.2 Function/Subroutine Documentation

6.2.2.1 subroutine aprep (real, dimension (ilg) FC, real, dimension (ilg) FG, real, dimension (ilg) FCS, real, dimension (ilg) FGS, real, dimension (ilg) PAICAN, real, dimension (ilg) PAICNS, real, dimension (ilg) FSVF, real, dimension (ilg) FSVFS, real, dimension (ilg) FRAIN, real, dimension (ilg) FSNOWC, real, dimension (ilg) FRAICS, real, dimension (ilg) FSNOCNS, real, dimension (ilg) RAICAN, real, dimension (ilg) RAICNS, real, dimension (ilg) SNOCAN, real, dimension (ilg) SNOCNNS, real, dimension (ilg) DISP, real, dimension (ilg) DISPS, real, dimension (ilg) ZOMLNC, real, dimension (ilg) ZOMLCS, real, dimension (ilg) ZOELNC, real, dimension (ilg) ZOELCS, real, dimension (ilg) ZOMLNG, real, dimension (ilg) ZOMLNS, real, dimension (ilg) ZOELNG, real, dimension (ilg) ZOELNS, real, dimension (ilg) CHCAP, real, dimension (ilg) CHCAPS, real, dimension (ilg) CMASSC, real, dimension (ilg) CMASCS, real, dimension (ilg) CWLCAP, real, dimension (ilg) CWFCAP, real, dimension (ilg) CWLCPS, real, dimension (ilg) CWFCPS, real, dimension (ilg) RBCOEF, real, dimension (ilg) ZPLIMC, real, dimension (ilg) ZPLIMG, real, dimension (ilg) ZPLMCS, real, dimension (ilg) ZPLMGS, real, dimension (ilg) HTCC, real, dimension (ilg) HTCS, real, dimension (ilg,ig) HTC, real, dimension (ilg,ig) FROOT, real, dimension (ilg,ig) FROOTS, real, dimension (ilg) WTRC, real, dimension (ilg) WTRS, real, dimension (ilg) WTRG, real, dimension (ilg) CMAI, real, dimension (ilg,ic) PAI, real, dimension (ilg,ic) PAIS, real, dimension (ilg,ic) AIL, real, dimension (ilg,ic) FCAN, real, dimension (ilg,ic) FCANS, real, dimension (ilg) PSIGND, real, dimension (ilg,icp1) FCANMX, real, dimension (ilg,icp1) ZOLN, real, dimension (ilg,ic) PAIMAX, real, dimension (ilg,ic) PAIMIN, real, dimension (ilg,ic) CWGTMX, real, dimension (ilg,ic) ZRTMAX, real, dimension (ilg,ic) PAIDAT, real, dimension (ilg,ic) HGTDAT, real, dimension (ilg,ig) THLIQ, real, dimension (ilg,ig) THICE, real, dimension (ilg,ig) TBAR, real, dimension (ilg) RCAN, real, dimension (ilg) SNCAN, real, dimension (ilg) TCAN, real, dimension (ilg) GROWTH, real, dimension (ilg) ZSNOW, real, dimension (ilg) TSNOW, real, dimension (ilg) FSNOW, real, dimension (ilg) RHOSNO, real, dimension (ilg) SNO, real, dimension (ilg) ZOORO, real, dimension (ilg) ZBLEND, real, dimension (ilg) ZPLMG0, real, dimension (ilg) ZPLMS0, real, dimension (ilg) TA, real, dimension (ilg) RHOAIR, real, dimension (ilg) RADJ, real, dimension (ilg) DLON, real, dimension (ilg) RHOSNI, real, dimension (ilg) DELZ, real, dimension (ilg,ig) DELZW, real, dimension (ilg,ig) ZBOTW, real, dimension (ilg,ig) THPOR, real, dimension (ilg,ig) THLMIN, real, dimension (ilg,ig) PSISAT, real, dimension (ilg,ig) BI, real, dimension (ilg,ig) PSIWL, real, dimension (ilg,ig) HCPS, integer, dimension (ilg,ig) ISAND, integer, dimension (ilg,ig) IL1, integer, dimension (ilg,ig) IL2, integer, dimension (ilg,ig) JL, integer, dimension (ilg,ig) IC, integer, dimension (ilg,ig) ICP1, integer, dimension (ilg,ig) IG, integer, dimension (ilg,ig) IDAY, integer, dimension (ilg,ig) IDISP, integer, dimension (ilg,ig) IZREF, integer, dimension (ilg,ig) IWF, integer, dimension (ilg,ig) IPAI, integer, dimension (ilg,ig) IHGT, real, dimension (ilg,ic,ig) RMAT, real, dimension (ilg,ic) H, real, dimension (ilg,ic) HS, real, dimension (ilg) CWCPAV, real, dimension (ilg) GROWA, real, dimension (ilg) GROWN, real, dimension (ilg) GROWB, real, dimension (ilg) RRESID, real, dimension (ilg) SRESID, real, dimension (ilg) FRTOT, real, dimension (ilg) FRTOTS, real, dimension (ilg,ic) FCANCMX, integer, dimension (ilg,ic) ICTEM, logical, dimension (ilg,ic) ctem_on, real, dimension (ilg,ic,ig) RMATC, real, dimension (ilg,ic) AILC, real, dimension (ilg,ic) PAIC, real, dimension (ilg,ic) AILCG, integer, dimension (ilg,ic) L2MAX, integer, dimension (ilg,ic) NOL2PFTS, real, dimension (ilg,ic) AILCGS, real, dimension (ilg,ic) FCANCS, real, dimension (ilg,ic) FCANC, real, dimension (ilg,ic) ZOLNC, real, dimension (ilg,ic) CMASVEGC, real, dimension (ilg,ic) SLAIC, integer, dimension (ilg,ic) ipeatland)

This subroutine is hard-coded to handle the standard four vegetation categories recognized by CLASS (needleleaf trees, broadleaf trees, crops and grass), so a call to abort is performed if the number of vegetation classes, IC, is not equal to 4. A set of diagnostic and accumulator arrays is then initialized to zero, and the liquid water suction in the soil is set to an arbitrarily high value.

Parameters

<i>fc</i>	Subarea fractional coverage of modelled area (X) []
<i>fg</i>	Subarea fractional coverage of modelled area (X) []
<i>fcs</i>	Subarea fractional coverage of modelled area (X) []
<i>fgs</i>	Subarea fractional coverage of modelled area (X) []
<i>paican</i>	Plant area index of canopy over bare ground (Λ_p) []
<i>paicns</i>	Plant area index of canopy over snow (Λ_p) []
<i>fsvf</i>	Sky view factor for bare ground under canopy (χ) []
<i>fsvfs</i>	Sky view factor for snow under canopy (χ) []
<i>frainc</i>	Fractional coverage of canopy by liquid water over snow-free subarea []
<i>fsnowc</i>	Fractional coverage of canopy by frozen water over snow-free subarea []
<i>fraics</i>	Fractional coverage of canopy by liquid water over snow-covered subarea []
<i>fsnoc</i>	Fractional coverage of canopy by frozen water over snow-covered subarea []
<i>raican</i>	Intercepted liquid water stored on canopy over bare ground (W_l) [kgm^{-2}]
<i>raicns</i>	Intercepted liquid water stored on canopy over snow (W_l) [kgm^{-2}]
<i>snocan</i>	Intercepted frozen water stored on canopy over bare soil (W_f) [kgm^{-2}]
<i>snocns</i>	Intercepted frozen water stored on canopy over snow (W_f) [kgm^{-2}]
<i>disp</i>	Displacement height of vegetation over bare ground (d) [m]
<i>disps</i>	Displacement height of vegetation over snow (d) [m]
<i>zomlnc</i>	Logarithm of roughness length for momentum of vegetation over bare ground []
<i>zomlcs</i>	Logarithm of roughness length for momentum of vegetation over snow []
<i>zoelnc</i>	Logarithm of roughness length for heat of vegetation over bare ground []
<i>zoelcs</i>	Logarithm of roughness length for heat of vegetation over snow []
<i>zomlng</i>	Logarithm of roughness length for momentum of bare ground []
<i>zomlns</i>	Logarithm of roughness length for momentum of snow []
<i>zoelng</i>	Logarithm of roughness length for heat of bare ground []
<i>zoelns</i>	Logarithm of roughness length for heat of snow []
<i>rbcoef</i>	Parameter for calculation of leaf boundary resistance (C_{rb})
<i>chcap</i>	Heat capacity of canopy over bare ground [$Jm^{-2}K^{-1}$]
<i>chcaps</i>	Heat capacity of canopy over snow [$Jm^{-2}K^{-1}$]
<i>cmassc</i>	Mass of canopy over bare ground [kgm^{-2}]
<i>cmasc</i>	Mass of canopy over snow [kgm^{-2}]
<i>cwlcap</i>	Storage capacity of canopy over bare ground for liquid water ($W_{l,max}$) [kgm^{-2}]
<i>cwfcap</i>	Storage capacity of canopy over bare ground for frozen water ($W_{f,max}$) [kgm^{-2}]
<i>cwlcps</i>	Storage capacity of canopy over snow for liquid water ($W_{l,max}$) [kgm^{-2}]
<i>cwfcps</i>	Storage capacity of canopy over snow for frozen water ($W_{f,max}$) [kgm^{-2}]
<i>zplimc</i>	Maximum water ponding depth for ground under canopy [m]
<i>zplimg</i>	Maximum water ponding depth for bare ground [m]
<i>zplmcs</i>	Maximum water ponding depth for ground under snow under canopy [m]
<i>zplmgs</i>	Maximum water ponding depth for ground under snow [m]
<i>htcc</i>	Diagnosed internal energy change of vegetation canopy due to conduction and/or change in mass [Wm^{-2}]
<i>htcs</i>	Diagnosed internal energy change of snow pack due to conduction and/or change in mass [Wm^{-2}]

<i>wtrc</i>	Diagnosed residual water transferred off the vegetation canopy [$kgm^{-2}s^{-1}$]
<i>wtrs</i>	Diagnosed residual water transferred into or out of the snow pack [$kgm^{-2}s^{-1}$]
<i>wtrg</i>	Diagnosed residual water transferred into or out of the soil [$kgm^{-2}s^{-1}$]
<i>cmai</i>	Aggregated mass of vegetation canopy [kgm^{-2}]
<i>froot</i>	Fraction of total transpiration contributed by soil layer over snow-free subarea []
<i>froots</i>	Fraction of total transpiration contributed by soil layer over snow-covered subarea []
<i>htc</i>	Diagnosed internal energy change of soil layer due to conduction and/or change in mass [Wm^{-2}]
<i>pai</i>	Plant area index of vegetation category over bare ground []
<i>pais</i>	Plant area index of vegetation category over snow []
<i>ail</i>	Leaf area index of vegetation category over bare ground []
<i>fcan</i>	Fractional coverage of vegetation category over bare ground (X_i) []
<i>fcans</i>	Fractional coverage of vegetation category over snow (X_i) []
<i>psignd</i>	Minimum liquid moisture suction in soil layers [m]
<i>ipeatland</i>	Peatland flag: 0 = not a peatland, 1= bog, 2 = fen
<i>fcanmx</i>	Maximum fractional coverage of modelled area by vegetation category []
<i>zoln</i>	Natural logarithm of maximum roughness length of vegetation category []
<i>paimax</i>	Maximum plant area index of vegetation category []
<i>paimin</i>	Minimum plant area index of vegetation category []
<i>cwgtmx</i>	Maximum canopy mass for vegetation category [kgm^{-2}]
<i>zrtmax</i>	Maximum rooting depth of vegetation category [m]
<i>paidat</i>	Optional user-specified value of plant area indices of vegetation categories to override CL↔ASS-calculated values []
<i>hgtat</i>	Optional user-specified values of height of vegetation categories to override CLASS-calculated values [m]
<i>thliq</i>	Volumetric liquid water content of soil layers (θ_l) [m^3m^{-3}]
<i>thice</i>	Frozen water content of soil layers under vegetation [m^3m^{-3}]
<i>tbar</i>	Temperature of soil layers [K]
<i>rcan</i>	Intercepted liquid water stored on canopy (W_l) [kgm^{-2}]
<i>sncan</i>	Intercepted frozen water stored on canopy (W_f) [kgm^{-2}]
<i>tcn</i>	Vegetation canopy temperature [K]
<i>growth</i>	Vegetation growth index []
<i>zsnow</i>	Depth of snow pack (z_s) [m]
<i>tsnow</i>	Snowpack temperature [K]
<i>fsnow</i>	Diagnosed fractional snow coverage []
<i>rhosno</i>	Density of snow (s) [kgm^{-3}]
<i>sno</i>	Mass of snow pack (W_s) [kgm^{-2}]
<i>ta</i>	Air temperature at reference height [K]
<i>rhoair</i>	Density of air [kgm^{-3}]
<i>dlon</i>	Longitude of grid cell (east of Greenwich) [degrees]
<i>z0oro</i>	Orographic roughness length [m]
<i>zblend</i>	Atmospheric blending height for surface roughness length averaging (z_b) [m]
<i>rhosni</i>	Density of fresh snow ($\rho_{s,f}$) [kgm^{-3}]
<i>zplmg0</i>	Maximum water ponding depth for snow-free subareas (user-specified when running MESH code) [m]
<i>zplms0</i>	Maximum water ponding depth for snow-covered subareas (user-specified when running M↔ESH code) [m]

<i>radj</i>	Latitude of grid cell (positive north of equator) [rad]
<i>delzw</i>	Permeable thickness of soil layer [m]
<i>zbotw</i>	Depth to permeable bottom of soil layer [m]
<i>thpor</i>	Pore volume in soil layer (θ p) [m^3m^{-3}]
<i>thlmin</i>	Residual soil liquid water content remaining after freezing or evaporation [m^3m^{-3}]
<i>psisat</i>	Soil moisture suction at saturation (Ψ sat) [m]
<i>bi</i>	Clapp and Hornberger empirical "b" parameter []
<i>psiwt</i>	Soil moisture suction at wilting point (Ψ w) [m]
<i>hcps</i>	Volumetric heat capacity of soil particles [Jm^{-3}]
<i>isand</i>	Sand content flag
<i>delz</i>	Soil layer thickness [m]
<i>ailcg</i>	GREEN LAI FOR USE WITH PHTSYN SUBROUTINE
<i>ailcgs</i>	GREEN LAI FOR CANOPY OVER SNOW SUB-AREA
<i>fcanc</i>	FRACTION OF CANOPY OVER GROUND FOR CTEM's 9 PFTs
<i>fcancs</i>	FRACTION OF CANOPY OVER SNOW FOR CTEM's 9 PFTs

In the 120 loop, the growth index for crops, GROWA, is calculated (if CLASS is not being run coupled to CTEM). This is done by referring to the three-dimensional array GROWYR, which contains values corresponding to the four Julian days of the year on which crops are planted, on which they reach maturity, on which harvesting begins, and on which the harvest is complete, for each ten-degree latitude half-circle in each hemisphere. These are generic, average dates, approximated using information gleaned from annual UN FAO (Food and Agriculture Organization) reports. (In the tropics, it is assumed that areas classified as agricultural are constantly under cultivation, so all four values are set to zero.)

First, the latitude of the modelled area is converted from a value in radians to a value from 1 to 18, IN, corresponding to the index of the latitude circle (1 for latitudes $80 - 90^\circ S$, 18 for latitudes $80 - 90^\circ N$). Then the hemisphere index, NL, is set to 1 for the Eastern Hemisphere, and 2 for the Western Hemisphere. If the planting date for the modelled area is zero (indicating a location in the tropics), GROWA is set to 1. Otherwise, GROWA is set to 1 if the day of the year lies between the maturity date and the start of the 54harvest, and to zero if the day of the year lies between the end of the harvest and the planting date. For dates in between, the value of GROWA is interpolated between 0 and 1. Checks are performed at the end to ensure that GROWA is not less than 0 or greater than 1. If the calculated value of GROWA is vanishingly small, it is set to zero.

In the 150 loop the other three growth indices are evaluated, as well as the vegetation heights and plant area indices for the four vegetation categories over snow-covered and snow-free ground. The background growth index for trees, GROWTH, is evaluated separately in subroutine CGROW. It varies from a value of 0 for dormant or leafless periods to 1 for fully-leafed periods, with a sixty-day transition between the two. When senescence begins, it is set instantaneously to -1 and thereafter increases over a sixty-day period back to 0. (The onset of spring budburst and fall senescence are triggered by near-zero values of the air temperature and the first soil layer temperature.) For needleleaf trees, the growth index GROWN is simply set to the absolute value of GROWTH. For broadleaf trees, the transition period is assumed to last thirty days instead of sixty, and so the growth index GROWB is set to the absolute value of double the value of GROWTH, with upper and lower limits of 1 and 0. Finally, the growth index of grasses is set to 1 all year round.

A branch in the code occurs next, depending on the value of the flag IHGT. If IHGT=0, the values of vegetation height calculated by CLASS are to be used. For trees and grass, the vegetation height under snow-free conditions is assumed to be constant year-round, and is calculated as 10 times the exponential of ZOLN, the logarithm of the maximum vegetation roughness length. For crops, this maximum height is multiplied by GROWA. If IHGT=1, vegetation heights specified by the user are utilized instead. This height H for each of the four vegetation categories is used to calculate the height HS over snow-covered areas. For needleleaf and broadleaf trees, HS is set to H. For crops and grass, HS is calculated by subtracting the snow depth ZSNOW from H, to account for the burying of short vegetation by snow.

Next a second branch occurs, depending on the value of the flag IPAI. If IPAI=0, the values of plant area index calculated by CLASS or CTEM are used. If CTEM is turned on (ICTEMMOD=1), the plant area index values over snow-free ground, PAI, for the four vegetation categories are set to the CTEM-generated values. If not, PAI, is determined for each vegetation category by interpolating between the annual maximum and minimum plant area indices using their respective growth index. If IPAI=1, plant area index values specified by the user are utilized instead. For trees, the plant area index over snow- covered ground, PAIS, is set to PAI. For crops and grass, if $H > 0$, PAIS is set to PAI scaled by the ratio of HS/H; otherwise, it is set to zero. Lastly, the leaf area indices for the

four vegetation categories over snow-free ground, AIL, are determined. If CTEM is turned on, these are assigned using the CTEM-generated values. If not, they are calculated on the basis of the PAI values. For needleleaf trees, AIL is estimated as 0.90 PAI; for broadleaf trees it is estimated as the excess PAI over the annual minimum value. For crops and grass AIL is assumed to be equal to PAI.

In the 175 loop, the fractional coverage of the modelled area by each of the four vegetation categories is calculated, for snow-free (FCAN) and snow-covered ground (FCANS). For needleleaf and broadleaf trees, FCAN is set to the maximum coverage FCANMX of the vegetation category, scaled by the snow-free fraction of the modelled area, 1-FSNOW. For crops and grass, this calculation is modified for cases where the plant area index has been calculated as falling below a threshold value owing to growth stage or burying by snow. This threshold value is assigned a value of 1.0; otherwise it is set to 1.) In such cases the vegetation coverage is assumed to become discontinuous, and so an additional multiplication by PAI is performed to produce a reduced value of FCAN, and PAI is reset to the threshold value. An identical procedure is followed to determine the FCANS values.

The areal fractions of each of the four CLASS subareas, vegetation over bare soil (FC), bare soil (FG), vegetation over snow (FCS) and snow (FGS) are then calculated, using the FCAN and FCANS values and FSNOW. Checks are carried out, and adjustments performed if necessary, to ensure that none of the four subareas is vanishingly small. The values of FSNOW and of the four FCANs and FCANSs are recalculated accordingly. Finally, checks are carried out to ensure that each of the four subareas is greater than zero, and that their sum is unity. If this is not the case, a call to abort is performed. In the last part of the 175 loop, the limiting ponding depth for surface water is determined for each of the four subareas. If the flag IWF is zero, indicating that lateral flow of water within the soil is to be neglected, these values are assigned as follows. If the index ISAND of the first soil layer is -3 or -4, indicating a rock surface or an ice sheet, the bare soil ponding limit, ZPLIMG, is set to 1 mm; otherwise ZPLIMG is set to 2 mm. If the fractional area of snow on bare soil is greater than zero, the subarea ponding limit ZPLMGS is set to the weighted average of ZPLIMG over the areas where snow has not buried vegetation and where it has buried crops, and to 3 mm over areas where it has buried grass; otherwise to zero. If the fractional area of canopy over bare soil is greater than zero, the subarea ponding depth ZPLIMC is set to the weighted average of 1 cm under trees and 3 mm under crops and grass; otherwise to zero. If the fractional area of canopy over snow is greater than zero, the subarea ponding depth ZPLMCS is also currently set to the weighted average of 1 cm under trees and 3 mm under crops and grass; otherwise to zero. Finally, if the flag IWF is greater than zero, indicating that lateral flow of soil water is being modelled, externally derived user-specified values of the ponding limit for the four subareas are assigned.

In loop 200, calculations are done related to the interception of water on vegetation. First, the plant area indices of the composite vegetation canopy over the snow-free and snow-covered subareas are calculated as weighted averages of the plant area indices of the four vegetation categories over each subarea. The liquid water interception capacity $W_{l,max}$ on each of the two subareas is calculated as $W_{l,max} = 0.20\Lambda_p$ where Λ_p is the plant area index of the composite canopy. This simple relation has been found to work well for a wide range of canopy types and precipitation events (see Verseghy et al, 1993). If either the average amount of liquid water on the canopy, RC_{CAN} , or the total canopy coverage, $FC+FCS$, is less than a small threshold value, the value of RC_{CAN} is stored in a residual water array RRESID, and RC_{CAN} is set to zero. Next the intercepted liquid water is partitioned between FC and FCS. First RC_{CAN} is re-evaluated as an average value over the canopy-covered area only, rather than over the whole modelled area. Then the intercepted liquid water amounts on vegetation over snow-free (RAICAN) and snow-covered areas (RAICNS) are calculated by making use of the relations $W_{l,0}/\Lambda_{p,0} = W_{l,s}/\Lambda_{p,s}$ and $W_l(X_0 + X_s) = W_{l,0}X_0 + W_{l,s}X_s$ where W_l is the liquid water on the canopy, X is the fractional area, and the subscripts 0 and s refer to snow-free and snow-covered areas respectively.

For snow interception on the canopy, a modified calculation of the plant area indices $\Lambda_{p,0}$ and $\Lambda_{p,s}$ is performed, assigning a weight of 0.7 to the plant area index of needleleaf trees, to account for the effect of needle clumping. The interception capacity for snow, $W_{f,max}$, is calculated following Bartlett et al. (2006) [Bartlett2006-xp], using a relation developed by Schmidt and Gluns (1991): $W_{f,max} = 6.0\Lambda_p[0.27 + 46.0\rho_{s,f}]$ where

In loops 250 and 275, calculations of the displacement height and the logarithms of the roughness lengths for heat and momentum are performed for the vegetated subareas. The displacement height d_i and the roughness length $z_{0,i}$ for the separate vegetation categories are obtained as simple ratios of the canopy height H : $d_i = 0.70H$
 $z_{0,i} = 0.10H$

The averaged displacement height d over the vegetated subareas is only calculated if the flag IDISP has been set to 1. If IDISP = 0, this indicates that the atmospheric model is using a terrain-following coordinate system, and thus the displacement height is treated as part of the "terrain". If DISP = 1, d is calculated as a logarithmic average over the vegetation categories: $X \ln(d) = \sum [X_i \ln(d_i)]$ where X is the fractional coverage of the subarea.

The averaged roughness length for momentum z_{0m} over the subarea is determined based on the assumption that averaging should be performed on the basis of the drag coefficient formulation. Thus, following Delage et al. (1999) [Delage1999-vj], and after Mason (1988): $X/\ln^2(z_b/z_{0m}) = \Sigma[X_i/\ln^2(z_b/z_{0i})]$

The averaged roughness length for heat z_{0e} over the subarea is calculated as a geometric mean over the vegetation categories: $z_{0e}z_{0mX} = \Pi(z_{0i}^{2X_i})$

In loop 300, calculations of the logarithms of the roughness lengths for heat and momentum are performed for the bare ground and snow-covered subareas. Background values of $\ln(z_{0m})$ for soil, snow cover, ice sheets and urban areas are passed into the subroutine through common blocks. In CLASS, urban areas are treated very simply, as areas of bare soil with a high roughness length. The subarea values of $\ln(z_{0m})$ for bare soil and snow are therefore adjusted for the fractional coverage of urban area. Values for the ratio between the roughness lengths for momentum and heat for bare soil and snow are also passed in via common blocks. These are used to derive subarea values of $\ln(z_{0e})$ from $\ln(z_{0m})$.

In the same loop the roughness length for peatlands is also calculated assuming a natural log of the roughness length of the moss surface is -6.57 (parameter stored in [ctem_params.f90](#))

In loop 325, an adjustment is applied to $\ln(z_{0m})$ if the effect of terrain roughness needs to be taken into account. If the surface orographic roughness length is not vanishingly small, its logarithm, LZ0ORO, is calculated. If it is greater than the calculated logarithm of the roughness length for momentum of any of the subareas, these are reset to LZ0ORO.

In loop 350, the canopy mass is calculated as a weighted average over the vegetation categories, for canopy over bare soil (CMASCC) and over snow (CMASCS). (For crops over bare soil, the mass is adjusted according to the growth index; for crops and grass over snow, the mass is additionally adjusted to take into account burying by snow.) If IDISP = 0, indicating that the vegetation displacement height is part of the "terrain", the mass of air within the displacement height is normalized by the vegetation heat capacity and added to the canopy mass. If IZREF = 2, indicating that the bottom of the atmosphere is taken to lie at the local roughness length rather than at the ground surface, the mass of air within the roughness length is likewise normalized by the vegetation heat capacity and added to the canopy mass. The canopy heat capacities over bare soil (CHCAP) and over snow (CHCAPS) are evaluated from the respective values of canopy mass and of intercepted liquid water and snow. The aggregated canopy mass CMAI is recalculated, and is used to determine the change in internal energy of the canopy, HTCC, owing to growth or disappearance of the vegetation.

In the 450 and 500 loops, the fraction of plant roots in each soil layer is calculated. If CLASS is being run coupled to CTEM, the CTEM-derived values are assigned. Otherwise, for each vegetation category the rooting depth ZROOT is set to the background maximum value, except in the case of crops, for which it is set to the maximum scaled by GROWA. If the soil permeable depth is less than ZROOT, ZROOT is set to this depth instead. Values are then assigned in the matrix RMAT, which stores the fraction of roots in each vegetation category for each soil layer. According to Feddes et al. (1974) [Feddes1974-ff], the fractional root volume $R(z)$ below a depth z is well represented for many varieties of plants by the following exponential function: $R(z) = a_1 \exp(-3.0z) + a_2$.

Making use of the boundary conditions $R(0) = 1$ and $R(z_r) = 0$, where z_r is the rooting depth ZROOT, it can be seen that the fraction of roots within a soil depth interval Δz can be obtained as the difference between $R(z)$ evaluated at the top (z_T) and bottom (z_B) of the interval: $R(\Delta z) = [\exp(-3.0z_T) - \exp(-3.0z_B)]/[1 - \exp(-3.0z_r)]$

The total fraction of roots in each soil layer, FROOT for snow-free areas and FROOTS for snow-covered areas, can then be determined as weighted averages over the four vegetation categories.

In loop 450, a leaf boundary resistance parameter C_{rb} , incorporating the plant area indices of the four vegetation subareas, is also calculated for later use in subroutine TSOLVC: $C_{rb} = C_l \Lambda_{p,i}^{0.5} / 0.75 \bullet [1 - \exp(-0.75 \Lambda_{p,i}^{0.5})]$ where C_l is a parameter that varies with the vegetation category. The aggregated value of C_{rb} is obtained as a weighted average over the four vegetation categories over bare ground and snow cover.

In loop 600, the sky view factor χ of the ground underlying the canopy is calculated for the vegetated subareas. The standard approach is to determine χ as an exponential function of the plant area index Λ_p : $\chi = \exp[-c\Lambda_p]$ where c is a constant depending on the vegetation category. The subarea values of χ are obtained as weighted averages over the four vegetation categories.

In the 650 loop, the fraction of the total transpiration of water by plants that is extracted from each soil layer is determined. This is done by weighting the values of FROOT and FROOTS calculated above by the relative soil moisture suction in each layer: $(\Psi_w - \Psi_i)/(\Psi_w - \Psi_{sat})$ where Ψ_i , the soil moisture suction in the layer, is

obtained as $\Psi_i = \Psi_{sat}(\theta_{l,i}/\theta_p)^{-b}$ In these equations Ψ_w is the soil moisture suction at the wilting point, Ψ_{sat} is the suction at saturation, $\theta_{l,i}$ is the volumetric liquid water content of the soil layer, θ_p is the pore volume, and b is an empirical parameter developed by Clapp and Hornberger (1978) [Clapp1978-898]. The layer values of FROOT and FROOTS are then re-normalized so that their sum adds up to unity. In this loop, the representative soil moisture suction PSIGND is also calculated for later use in the vegetation stomatal resistance formulation, as the minimum value of Ψ_i and Ψ_w over all the soil layers.

Finally, in loop 800 the aggregated canopy plant area indices PAICAN and PAICNS are set back to their original values, from the modified values used for the snow interception calculations above; and if CLASS is being run coupled with CTEM, a set of CTEM-related calculations is performed.

6.3.1 Detailed Description

Canadian Terrestrial Ecosystem Model (CTEM) Carbon Balance Subroutine.

unless mentioned all pools are in kg c/m2 unless mentioned all fluxes are in units of u-mol co2/m2.sec

6.3.2 Function/Subroutine Documentation

6.3.2.1 subroutine balcar (real, dimension(ilg,icc) *gleafmas*, real, dimension(ilg,icc) *stemmass*, real, dimension(ilg,icc) *rootmass*, real, dimension(ilg,icc) *bleafmas*, real, dimension(ilg,iccp1) *litrmass*, real, dimension(ilg,iccp1) *soilcmas*, real, dimension(ilg,icc) *ntchlveg*, real, dimension(ilg,icc) *ntchsvg*, real, dimension(ilg,icc) *ntchrveg*, real, dimension(ilg,icc) *tltrleaf*, real, dimension(ilg,icc) *tltrstem*, real, dimension(ilg,icc) *tltrroot*, real, dimension(ilg,icc) *glcaemls*, real, dimension(ilg,icc) *blcaemls*, real, dimension(ilg,icc) *stcaemls*, real, dimension(ilg,icc) *rtcaemls*, real, dimension(ilg,icc) *ltrcemls*, real, dimension(ilg,iccp1) *ltresveg*, real, dimension(ilg,iccp1) *scresveg*, real, dimension(ilg,iccp1) *humtrsvg*, real, dimension(ilg,icc) *pglfmass*, real, dimension(ilg,icc) *pblfmass*, real, dimension(ilg,icc) *pstemass*, real, dimension(ilg,icc) *protmass*, real, dimension(ilg,iccp1) *plitmass*, real, dimension(ilg,iccp1) *psocmass*, real, dimension(ilg) *vgbiomas*, real, dimension(ilg,icc) *repro_cost*, real, dimension(ilg) *pvgbioms*, real, dimension(ilg) *gavglts*, real, dimension(ilg) *pgavltms*, real, dimension(ilg) *gavgscms*, real, dimension(ilg) *pgavscms*, real, dimension(ilg) *galtcels*, real, dimension(ilg) *repro_cost_g*, real, dimension(ilg) *npp*, real, dimension(ilg) *autores*, real, dimension(ilg) *hetrores*, real, dimension(ilg) *gpp*, real, dimension(ilg) *nep*, real, dimension(ilg) *litres*, real, dimension(ilg) *socres*, real, dimension(ilg) *dstcemls*, real, dimension(ilg) *nbp*, real, dimension(ilg) *litrfall*, real, dimension(ilg) *humiftrs*, integer *il1*, integer *il2*, integer, dimension (ilg) *ipeatland*, real, dimension(ilg) *Cmassmas*, real, dimension(ilg) *pCmassmas*, real, dimension(ilg) *nppmosstep*, real, dimension(ilg) *litrfallmoss*, real, dimension(ilg) *litrmsmoss*, real, dimension(ilg) *plitrmsmoss*, real, dimension(ilg) *ltrestepmoss*, real, dimension(ilg) *humicmosstep*)

Parameters

<i>il1</i>	other variables: il1=1
<i>il2</i>	other variables: il2=ilg
<i>stemmass</i>	pools (after being updated): stem mass for each of the 9 ctem pfts
<i>rootmass</i>	pools (after being updated): root mass for each of the 9 ctem pfts
<i>gleafmas</i>	pools (after being updated): green leaf mass for each of the 9 ctem pfts
<i>bleafmas</i>	pools (after being updated): brown leaf mass for each of the 9 ctem pfts
<i>litrmas</i>	pools (after being updated): litter mass over the 9 pfts and the bare fraction of the grid cell
<i>soilcmas</i>	pools (after being updated): soil carbon mass over the 9 pfts and the bare fraction of the grid cell
<i>ntchlveg</i>	fluxes for each pft: net change in leaf biomass
<i>ntchsveg</i>	fluxes for each pft: net change in stem biomass
<i>ntchrveg</i>	fluxes for each pft: net change in root biomass the net change is the difference between allocation and autotrophic respiratory fluxes
<i>tltrleaf</i>	fluxes for each pft: total leaf litter falling rate
<i>tltrstem</i>	fluxes for each pft: total stem litter falling rate
<i>tltrroot</i>	fluxes for each pft: total root litter falling rate
<i>glcaemls</i>	fluxes for each pft: carbon emission losses mainly due to fire: green leaf carbon emission losses
<i>blcaemls</i>	fluxes for each pft: carbon emission losses mainly due to fire: brown leaf carbon emission losses
<i>stcaemls</i>	fluxes for each pft: carbon emission losses mainly due to fire: stem carbon emission losses
<i>rtcaemls</i>	fluxes for each pft: carbon emission losses mainly due to fire: root carbon emission losses
<i>ltrcemls</i>	fluxes for each pft: carbon emission losses mainly due to fire: litter carbon emission losses
<i>ltresveg</i>	fluxes for each pft: litter respiration for each pft + bare fraction
<i>scresveg</i>	fluxes for each pft: soil c respiration for each pft + bare fraction
<i>humtrsvg</i>	fluxes for each pft: humification for each pft + bare fraction
<i>pglflmass</i>	pools (before being updated): previous green leaf mass
<i>pblflmass</i>	pools (before being updated): previous brown leaf mass
<i>pstemmass</i>	pools (before being updated): previous stem mass
<i>protmass</i>	pools (before being updated): previous root mass
<i>plitmass</i>	pools (before being updated): previous litter mass
<i>psocmass</i>	pools (before being updated): previous soil c mass
<i>npp</i>	grid averaged flux: net primary productivity
<i>vgbiomas</i>	pools (after being updated): grid averaged pools: vegetation biomass
<i>pvgbioms</i>	pools (before being updated): grid average pools: previous vegetation biomass
<i>gavgltns</i>	pools (after being updated): grid averaged pools: litter mass
<i>pgavltns</i>	pools (before being updated): grid average pools: previous litter mass
<i>gavgscms</i>	pools (after being updated): grid averaged pools: soil carbon mass
<i>pgavscms</i>	pools (before being updated): grid average pools: previous soil c mass
<i>autores</i>	grid averaged flux: autotrophic respiration
<i>hettores</i>	grid averaged flux: heterotrophic respiration
<i>gpp</i>	grid averaged flux: gross primary productivity
<i>nep</i>	grid averaged flux: net primary productivity

<i>litrres</i>	grid averaged flux: litter respiration
<i>socres</i>	grid averaged flux: soil carbon respiration
<i>dstcemls</i>	grid averaged flux: carbon emission losses due to disturbance, mainly fire
<i>nbp</i>	grid averaged flux: net biome productivity
<i>litrfall</i>	grid averaged flux: combined (leaves, stem, and root) total litter fall rate
<i>humiftrs</i>	grid averaged flux: humification
<i>repro_cost</i>	pools (after being updated): amount of C transferred to litter due to reproductive tissues
<i>ipeatland</i>	Peatland flag, non-peatlands = 0
<i>cmossmas</i>	moss biomass C (kgC/m2)
<i>pcmossmas</i>	moss biomass C at the previous time step (kgC/m2)
<i>nppmosstep</i>	moss npp (kgC/m2/timestep)
<i>litrfallmoss</i>	moss litter fall (kgC/m2/timestep)
<i>litrmsmoss</i>	moss litter C (kgC/m2)
<i>plitrmsmoss</i>	moss litter C at the previous time step (kgC/m2)
<i>ltrestepmoss</i>	litter respiration from moss (kgC/m2/timestep)
<i>humicmosstep</i>	moss humification (kgC/m2/timestep)
<i>galtcels</i>	grid averaged flux: carbon emission losses from litter
<i>repro_cost_g</i>	grid averaged flux: amount of C used to generate reproductive tissues

to check c budget we go through each pool for each vegetation type.

6.4.1 Detailed Description

Biomass To Structural Attributes Conversion Subroutine.

The time-varying biomass in the leaves (C_L), stem (C_S) and root (C_R) components is used to calculate the structural attributes of vegetation for the energy and water balance calculations by CLASS.

Leaf biomass is converted to LAI using specific leaf area (SLA , $m^2 (kg C)^{-1}$), which itself is assumed to be a function of leaf lifespan (τ_L ; see also [ctem_params.f90](#))

$$SLA = \gamma_L \tau_L^{-0.5} LAI = C_L SLA$$

where γ_L is a constant with value equal to $25 \text{ m}^2 (\text{kg C})^{-1} \text{ yr}^{0.5}$. The vegetation height (H ; m) is calculated for tree, crop and grass PFTs as

$$H = \min(10.0 C_S^{0.385}, 45) \text{ for trees}$$

$$H = (C_S + C_L)^{0.385} \text{ for crops}$$

$$H = 3.5(C_{L,g} + 0.55 C_{L,b})^{0.5} \text{ for grasses}$$

where $C_{L,g}$ is the green leaf biomass and $C_{L,b}$ is the brown leaf biomass that is scaled by 0.55 to reduce its contribution to the plant height. CTEM explicitly tracks brown leaf mass for grass PFTs. The turnover of green grass leaves, due to normal aging or stress from drought and/or cold, does not contribute to litter pool directly as the leaves first turn brown. The brown leaves themselves turnover to litter relatively rapidly ($\tau_{L,b} = 0.1 \tau_L$).

In peatlands the vegetation height is calculated as (Wu et al. 2016) [Wu2016-zt]

$$H = \min(10.0, 3.0 C_S^{0.385}) \text{ for trees}$$

$$H = \min(1.0, 0.25(C_S^{0.2})) \text{ for shrubs}$$

$$H = \min(1.0, (C_{L,g} + 0.55 C_{L,b})^{0.3}) \text{ for grasses and sedges}$$

CTEM dynamically simulates root distribution and depth in soil following (Arora and Boer, 2003) [Arora2003838]. The root distribution takes an exponential form and roots grow and deepen with increasing root biomass. The cumulative root fraction at depth z is given by

$$f_R(z) = 1 - \exp(-\iota z)$$

Rooting depth (d_R ; m), which is defined to be the depth containing 99 % of the root mass, is found by setting z equal to d_R and $f_R = 0.99$, which yields

$$d_R = \frac{-\ln(1 - f_R)}{\iota} = \frac{-\ln(1 - 0.99)}{\iota} = \frac{4.605}{\iota}.$$

The parameter ι that describes the exponential root distribution is calculated as

$$\iota = \bar{\iota} \left(\frac{\overline{C_R}}{C_R} \right)^{0.8},$$

where $\bar{\iota}$ represents the PFT-specific mean root distribution profile parameter and $\overline{C_R}$ the average root biomass derived from Jackson et al. (1996) [Jackson1996-va] (see also [ctem_params.f90](#)). Equation for ι above yields a lower (higher) value of ι than $\bar{\iota}$ when root biomass C_R is higher (lower) than the PFT-specific mean root biomass $\overline{C_R}$, resulting in a deeper (shallower) root profile than the mean root profile.

The rooting depth d_R is checked to ensure it does not exceed the soil depth. If so, d_R is set to the soil depth and ι is recalculated as $\iota = 4.605/d_R$ (see Eq. rootterm1 for derivation of 4.605 term). The new value of ι is used to determine the root distribution profile adjusted to the shallower depth. Finally, the root distribution profile is used to calculate fraction of roots in each of the model's soil layers.

6.4.2 Function/Subroutine Documentation

6.4.2.1 subroutine bio2str (real, dimension(ilg,icc) gleafmas, real, dimension(ilg,icc) bleafmas, real, dimension(ilg,icc) stemmass, real, dimension(ilg,icc) rootmass, integer il1, integer il2, real, dimension(ilg,icc) fcancmx, real, dimension(ilg,ignd) zbotw, real, dimension(ilg,ignd) delzw, integer, dimension(ican) nol2pfts, real, dimension(ilg) soildpth)

Parameters

<i>il1</i>	input: il1=1
<i>il2</i>	input: il2=ilg
<i>nol2pfts</i>	input: number of level 2 pfts
<i>gleafmas</i>	input: green or live leaf mass in kg c/m2, for the 9 pfts
<i>bleafmas</i>	input: brown or dead leaf mass in kg c/m2, for the 9 pfts
<i>stemmass</i>	input: stem biomass in kg c/m2, for the 9 pfts
<i>rootmass</i>	input: root biomass in kg c/m2, for the 9 pfts
<i>fcancmx</i>	input: max. fractional coverages of ctem's 9 pfts. this is different from fcanc and fcancs (which may vary with snow depth). fcancmx doesn't change, unless of course its changed by land use change or dynamic vegetation.
<i>delzw</i>	input: thicknesses of the 3 soil layers
<i>zbotw</i>	input: bottom of soil layers
<i>soildpth</i>	input: soil depth (m)

Constants and parameters are located in [ctem_params.f90](#)

class' original root parameterization has deeper roots than ctem's default values based on literature. in the coupled model this leads to lower evapotranspiration (et) values. an option is provided here to deepen roots, but this will also increase photosynthesis and vegetation biomass slightly, due to more access to soil water. so while use of deeper roots is desirable in the coupled global model, one may decide to use ctem's default parameterization for stand alone simulations, and set deeproots to .false.

—— 1. conversion of leaf biomass into leaf area index ——

find specific leaf area (sla, m2/kg) using leaf life span

convert leaf biomass into lai. brown leaves could have less lai than the green leaves for the same leaf mass. for now we assume sla of brown leaves is fracbofg times that of green leaves.

also find stem area index as a function of stem biomass

plant area index is sum of green and brown leaf area indices and stem area index

make class see some minimum pai, otherwise it runs into numerical problems

get fcancmx weighted leaf area index for use by class needle leaf evg + dcd = total needle leaf broad leaf evg + dcd
 cld + dcd dry = total broad leaf crop c3 + c4 = total crop grass c3 + c4 = total grass also add brown lai. note that
 although green + brown lai is to be used by class for energy and water balance calculations, stomatal conductance
 estimated by the photosynthesis subroutine is only based on green lai. that is although both green+brown leaves
 intercept water and light, only the green portion photosynthesizes. also lump stem and plant area indices for class'
 4 pfts

for crops and grasses set the minimum lai to a small number, other wise class will never run tsolve and thus phtsyn
 and ctem will not be able to grow crops or grasses.

—— 2. conversion of stem biomass into roughness length ——

class uses log of roughness length (zoln) as an input parameter. when vegetation grows and dies as per ctem, then
 zoln is provided by ctem.

1. convert stem biomass into vegetation height for trees and crops, and convert leaf biomass into vegetation
 height for grass

2. convert vegetation height into roughness length & take its log

3. lump this for ctem's 9 pfts into class' 4 pfts

Determine the vegetation height of the peatland shrubs shrubs in mbbog maximum 0.3 m average 0.18 m
 (Bubier et al. 2011) grass and herbs avg 0.3m, min 0.05 max 0.8 low shrub avg 0.82, min 0.10, max 2.00 tall
 shrub avg.3.76, min 2.3, max 5.00 (Hopkinson et al. 2005) The Canadian wetland vegetation classification
 graminoids include grass,rush,reed,sedge forb is all non-graminoids herbaceous plants shrubs dwarf <0.1m,
 low (0.1 to 0.5), medium 0.5 to 1.5, tall >1.5 trees > 5 m

—— 3. estimating fraction of roots in each soil layer for —— ctem's each vegetation type, using root biomass
 ——

estimate parameter b of variable root profile parameterization

use b to estimate 99% rooting depth

if estimated rooting depth is greater than soil depth, or the maximum rooting depth then adjust rooting depth and parameter alpha

also find "a" (parameter determining root profile). this is the "a" which depends on time varying root biomass

using parameter "a" we can find fraction of roots in each soil layer just like class

if rootdepth is shallower than the bottom of current layer and is deeper than bottom of the previous top layer

if rootdepth is shallower than the bottom of 2nd layer

if rootdepth is shallower than the bottom of 3rd layer or even the deeper layer (ignd>3)

make sure all fractions (of roots in each layer) add to one.

lump rmatctem(i,9,ignd) into rmatc(i,4,ignd) for use by class

----- 4. calculate storage lai -----

need a minimum slai to be able to grow from scratch. consider this as model seeds.

— 5. calculate total vegetation biomass for each ctem pft, and — ----- canopy mass for each class pft

since class uses canopy mass and not total vegetation biomass as an input, we find canopy mass as a sum of stem and leaf mass, for each class pft, i.e. only above ground biomass.

if there is no vegetation canopy mass will be abszero. this should essentially mean more bare ground, but since we are not changing fractional coverages at present, we pass a minimum canopy mass to class so that it doesn't run into numerical problems.

— 6. calculate albedo for class' 4 pfts based on specified — ----- albedos of ctem 9 pfts and their fractional coveraes -----

6.5.2.1 subroutine canadd (integer *IWATER*, real, dimension (ilg) *R*, real, dimension (ilg) *TR*, real, dimension (ilg) *S*, real, dimension (ilg) *TS*, real, dimension (ilg) *RAICAN*, real, dimension (ilg) *SNOCAN*, real, dimension (ilg) *TCAN*, real, dimension (ilg) *CHCAP*, real, dimension (ilg) *HTCC*, real, dimension (ilg) *ROFC*, real, dimension (ilg) *ROVG*, real, dimension (ilg) *PCPN*, real, dimension (ilg) *PCPG*, real, dimension (ilg) *FI*, real, dimension (ilg) *FSVF*, real, dimension (ilg) *CWLCAP*, real, dimension (ilg) *CWFCAP*, real, dimension (ilg) *CMASS*, real, dimension (ilg) *RHOSNI*, real, dimension (ilg) *TSURX*, real, dimension (ilg) *RDRIP*, real, dimension (ilg) *SDRIP*, integer *ILG*, integer *IL1*, integer *IL2*, integer *JL*)

Parameters

<i>r</i>	Rainfall rate over subarea in question [ms^{-1}]
<i>tr</i>	Temperature of rainfall [C]
<i>s</i>	Snowfall rate over subarea in question [ms^{-1}]
<i>ts</i>	Temperature of snowfall [C]
<i>raican</i>	Intercepted liquid water stored on the canopy [kgm^{-2}]($W_{l,c}$)
<i>snocan</i>	Intercepted frozen water stored on the canopy [kgm^{-2}]($W_{f,c}$)
<i>tcn</i>	Temperature of vegetation canopy [K](T_c)
<i>chcap</i>	Heat capacity of vegetation canopy [$Jm^{-2}K^{-1}$](C_c)
<i>htcc</i>	Internal energy change of canopy due to changes in temperature and/or mass [Wm^{-2}](I_c)
<i>rofc</i>	Liquid/frozen water runoff from vegetation [$kgm^{-2}s^{-1}$]
<i>rovg</i>	Liquid/frozen water runoff from vegetation to ground surface [$kgm^{-2}s^{-1}$]
<i>pcpn</i>	Precipitation incident on snow pack [$kgm^{-2}s^{-1}$]
<i>pcpg</i>	Precipitation incident on ground [$kgm^{-2}s^{-1}$]
<i>fi</i>	Fractional coverage of subarea in question on modelled area $\square(X_i)$
<i>fsvf</i>	Sky view factor of surface under vegetation canopy []
<i>cwlcap</i>	Interception storage capacity of vegetation for liquid water [kgm^{-2}]
<i>cwfcap</i>	Interception storage capacity of vegetation for frozen water [kgm^{-2}]($W_{f,max}$)
<i>cmass</i>	Mass of vegetation canopy [kgm^{-2}]
<i>rhosni</i>	Density of fresh snow [kgm^{-3}]
<i>tsurx</i>	Ground or snow surface temperature of subarea [K]

The calculations in this subroutine are performed if the rainfall or snowfall rates over the modelled area are greater than zero, or if the intercepted liquid water RAICAN or frozen water SNOCAN is greater than zero (to allow for unloading). The throughfall of rainfall or snowfall incident on the canopy, RTHRU or STHRU, is calculated from FSVF, the canopy gap fraction or sky view factor. The remaining rainfall or snowfall is assigned to interception, as RINT and SINT. The resulting temperature of liquid water on the canopy, TRCAN, is calculated as a weighted average of RAICAN at the canopy temperature TCAN, and RINT at the rainfall temperature TR. The resulting temperature of frozen water on the canopy, TSCAN, is calculated as a weighted average of SNOCAN at the canopy temperature TCAN, and SINT at the snowfall temperature TS.

Calculations are now done to ascertain whether the total liquid water on the canopy exceeds the liquid water interception capacity CWLCAP. If such is the case, this excess is assigned to RDRIP, water dripping off the canopy. The rainfall rate reaching the surface under the canopy is calculated as RDRIP + RTHRU, and the temperature of this water flux is calculated as a weighted average of RDRIP at a temperature of TRCAN, and RTHRU at the original rainfall temperature TR. The remaining intercepted water becomes CWLCAP. Otherwise, the rainfall rate reaching the surface under the canopy is set to RTHRU, and the liquid water on the canopy RAICAN is augmented by RINT.

Interception and unloading of snow on the canopy is calculated using a more complex method. The amount of snow intercepted during a snowfall event over a time step, $\Delta W_{f,i}$, or SLOAD, is obtained from the initial intercepted snow amount $W_{f,c}$ and the interception capacity $W_{f,max}$, following Hedstrom and Pomeroy (1998), as:

$$\Delta W_{f,i} = (W_{f,max} \sim W_{f,c})[1 \sim \exp(-S_{int}/W_{f,max})]$$

where S_{int} is the amount of snow incident on the canopy during the time step. The amount of snow not stored by interception, SWXCES, is calculated as SINT – SLOAD. Between and during precipitation events, snow is unloaded from the canopy through wind gusts and snow densification. These effects of these processes are estimated using an empirical exponential relationship for the snow unloading rate $W_{f,u}$ or SNUNLD, again following Hedstrom and Pomeroy (1998):

$$W_{f,u} = W_{f,c} + \Delta W_{f,i} \exp(-U \Delta t)$$

where U is a snow unloading coefficient, assigned a value of $0.1d^{-1}$ or $1.157 * 10^{-6}s^{-1}$. The sum of SWXCES and SNUNLD is assigned to SDRIP, the snow or frozen water falling off the canopy. The snowfall rate reaching the surface under the canopy is calculated as SDRIP + STHRU, and the temperature of this water flux is calculated as a weighted average of SDRIP at a temperature of TSCAN, and STHRU at the original snowfall temperature TS. The frozen water stored on the canopy is recalculated as SNOCAN + SINT – SWXCES - SNUNLD. Otherwise, the snowfall rate reaching the surface under the canopy is set to STHRU, and SNOCAN is augmented by SINT.

In the final section of the subroutine, the initial heat capacity and temperature of the canopy are saved in temporary variables. The new canopy heat capacity is calculated as a weighted average over the specific heats of the liquid

and frozen water stored on the canopy and the canopy mass. The canopy temperature is calculated as a weighted average over the stored liquid and frozen water at the updated temperatures TRCAN and TSCAN, and the vegetation mass at the original temperature TCAN. Then the change in internal energy I_c of the vegetation canopy as a result of the water movement above is calculated as the difference in I_c before and after these processes:

$$\Delta I_c = X_i \Delta [C_c T_c] / \Delta t$$

where C_c represents the canopy heat capacity, T_c the canopy temperature, Δt the length of the time step, and X_i the fractional coverage of the subarea under consideration relative to the modelled area.

Finally, the rainfall and snowfall temperatures are converted to degrees C. (In the absence of precipitation, both are set equal to the surface temperature of the subarea to avoid floating point errors in later subroutines.) For subareas with a snow cover (IWATER = 2), the water running off the canopy and the precipitation incident on the snow pack are updated using RDRIP and SDRIP. For subareas without snow cover (IWATER = 1), the water running off the canopy is updated using RDRIP and SDRIP, the precipitation incident on the snow pack is augmented by SDRIP, and the precipitation incident on bare ground is augmented by RDRIP.

<i>alirsc</i>	Visible/near-IR albedo of snow under vegetation []

The transmissivity τ_c of a vegetation canopy to shortwave radiation is obtained by applying a form of Beer's law of radiation transfer in non-scattering media: $\tau_c = \exp[-\kappa\Lambda_p]$ where κ is the canopy extinction coefficient and Λ_p is the plant area index. The extinction coefficient is calculated after Goudriaan (1988) **[Gold1958-ng]** as $\kappa = \epsilon O / \cos(Z)$ where epsilon is a correction factor less than or equal to 1, accounting for forward-scattering of radiation and non-random leaf distributions (i.e. clumping), O represents the mean projected leaf area fraction perpendicular to the incoming radiation, and Z is the zenith angle of the incoming radiation. For crops, grass and needleleaf trees, the distribution of leaf angles is assumed to be spherical, and thus O = 0.5. For broadleaf trees, the preferred leaf orientation tends to be horizontal; thus O = cos(Z).

In the clear-sky case, incoming shortwave radiation is dominated by the direct beam; thus, the transmissivity for clear skies $\tau_{c,0}$ is evaluated by simply setting Z to Z_s , the solar zenith angle. An extensive search of the literature

for values of epsilon appropriate to the four vegetation categories yielded the following results for the extinction coefficient:

$$\kappa = 0.3/\cos(Z_s)(\text{needleleaftrees}) \quad \kappa = 0.4(\text{broadleaftrees, fullcanopy}) \quad \kappa = 0.4/\cos(Z_s)(\text{broadleaftrees, leafless}) \\ \kappa = 0.4/\cos(Z_s)(\text{cropsandgrass})$$

In the visible range of the shortwave spectrum, scattering is less important because of high leaf absorptivities. The following results were obtained for visible radiation:

$$\kappa = 0.4/\cos Z_s(\text{needleleaftrees}) \quad \kappa = 0.7(\text{broadleaftrees, fullcanopy}) \quad \kappa = 0.4/\cos Z_s(\text{broadleaftrees, leafless}) \\ \kappa = 0.5/\cos Z_s(\text{cropsandgrass})$$

In the case of overcast skies, the hemispherical distribution of incoming shortwave radiation is modelled using the generally accepted "standard overcast sky" distribution (e.g. Steven and Unsworth, 1980), where the shortwave radiation $D(Z)$ emanating from a sky zenith angle Z is approximated as

$$D(Z) = D(0)[(1 + 1.23\cos Z)/2.23].$$

Integration of the cloudy-sky transmissivity $\tau_{c,cloudy}$ over the sky hemisphere is performed using a simple weighting function proposed by Goudriaan (1988) [**Gold1958-ng**] :

$$\tau_{c,cloudy} = 0.3\tau_c(Z = 15^\circ) + 0.5\tau_c(Z = 45^\circ) + 0.2\tau_c(Z = 75^\circ)$$

The albedo α_c of a vegetation canopy is, like the transmissivity, dependent in principle on the zenith angle Z of the incoming radiation and the mean projected leaf area fraction O . However, in practice the observed diurnal and seasonal variation of vegetation albedo tends to be slight for closed canopies or for radiation zenith angles larger than a few degrees. Since the former is generally true in the tropics and the latter in the extratropics, the diurnal variation of visible and near-infrared canopy albedo is neglected in CLASS.

Corrections are applied to the average albedos to account for the effects of intercepted snow on the canopy and incomplete canopy closure. The presence of snow on the canopy will increase the albedo; this increase will be larger in the visible range of the spectrum, since the visible albedo of vegetation is typically very small. Making use of data presented in Bartlett et al. (2015) [**Bartlett2015-gw**], the visible albedo of snow-covered vegetation is set to 0.27 and near-infrared albedo to 0.38.

If the canopy closure is incomplete, a fraction χ of the ground or snow under the canopy will be visible through gaps in it. This fraction is equal to the sky view factor of the underlying surface, which is calculated using an equation analogous to that for the canopy transmissivity, as an exponential function of the plant area index Λ_p :

$$\chi = \exp[-c\Lambda_p]$$

where c is a constant depending on the vegetation category. The overall albedo α_T is calculated as a weighted average of the canopy albedo and the underlying ground or snow albedo (the latter weighted by the canopy transmissivity, to account for the decreased downwelling shortwave radiation at the surface):

$$\alpha_T = (1 - \chi)\alpha_c + \chi\tau_c\alpha_0$$

where α_0 is the albedo of the surface under the canopy.

At the beginning of the subroutine, values are assigned to exponentiation terms and a series of work arrays is initialized to zero. Then the transmissivity and albedo of each vegetation category are calculated in turn, first over bare soil and then over a snow pack. After each of the latter sets of calculations, consistency checks are carried out to ensure that the calculated albedos and transmissivities are not less than 0 or greater than 1, and that the transmissivity is not greater than 90% of the non-reflected radiation.

The clear-sky and cloudy-sky transmissivities in the visible range are calculated first, and then the clear-sky and cloudy-sky transmissivities in the total shortwave spectrum, using the extinction coefficient equations above. (For broadleaf trees, the minimum of the full-canopy and leafless calculated values is used.) The overall transmissivity in the visible range at the current time step is obtained as an average of the clear and cloudy-sky values, weighted according to the fractional cloud cover. The effective overall extinction coefficient $CXTEFF$ in the visible range is computed for use later on in the stomatal resistance calculation. The overall transmissivity for the entire shortwave spectrum at the current time step is similarly obtained as an average of the clear and cloudy-sky values, weighted according to the fractional cloud cover. The near-infrared transmissivity is calculated from the total and visible transmissivities, making use of the assumption that visible and near-infrared radiation each typically comprise 50% of the incoming shortwave radiation. Lastly, the aggregated visible and near-infrared transmissivities for the bulk canopy are incremented using the current values weighted by the fractional coverage of the vegetation category. At the end, the sum is normalized by the total fractional vegetation coverage in the subarea.

For the albedos, first the sky view factor and the near-infrared albedo of snow-covered vegetation are calculated. Next, a branch directs further processing depending on the value of the flag IALC. If IALC = 0, the CLASS-calculated visible and near-infrared vegetation albedos are used. These albedos are corrected for the presence of intercepted snow, using an average of the snow-covered and background snow-free albedos weighted according to FSN_{\leftarrow} / OWC over snow-free, and $FSNOCS$ over snow-covered subareas (representing the ratio of the amount of snow present on the canopy relative to the interception capacity). The correction for incomplete canopy closure is applied to the resulting visible and near-infrared albedos as described above. If IALC = 1, user-specified albedos for the vegetation canopy are used instead of the CLASS values. These are assumed to incorporate the effects of incomplete canopy closure, but not of the presence of snow. Thus the CLASS values for the albedo of snow-covered vegetation and the albedo of snow under the canopy are still used in the averaging. Finally, the aggregated visible and near-infrared albedos for the bulk canopy are incremented using the current values weighted by the fractional coverage of the vegetation category. At the end, the sum is normalized by the total fractional vegetation coverage in the subarea.

In the final section, the stomatal resistance r_c of the vegetation canopy is determined. Based on the analysis of Schulze et al. (1995), the unstressed stomatal resistance $r_{c,u}$ for a given vegetation category can be calculated as a function of the incoming visible shortwave radiation $K \downarrow$:

$$r_{c,u} = r_{s,min} \kappa_e / \ln[K \downarrow + K \downarrow_{1/2} / \kappa_e / K \downarrow \exp(-\kappa_e \Lambda) + K \downarrow_{1/2} / \kappa_e]$$

where $r_{s,min}$ is the minimum stomatal resistance for the vegetation category, κ_e is the extinction coefficient for visible radiation (CXTEFF above), Λ is the leaf area index, and $K \downarrow_{1/2}$ is the value of $K \downarrow$ at which $r_{c,u} = 2r_{s,min}$.

Suboptimum environmental conditions for transpiration may lead to stresses on the plant, causing the stomatal resistance to be greater than its unstressed value. The effects of these stresses are modelled by defining functions of the air temperature T_a , the air vapour pressure deficit Δe , and the soil moisture suction Ψ_s . These functions are used to derive $r_{c,i}$ of each vegetation category on the basis of $r_{c,u,i}$:

$$r_{c,i} = f(T_a) f(\Delta e) f(\Psi_s) * r_{c,u,i}$$

The air temperature function $f(T_a)$ has a value of 1 for temperatures between $5^\circ C$ and $40^\circ C$, and an arbitrary large value of 250 for temperatures less than $-5^\circ C$ and greater than $50^\circ C$. Between these points it varies in a linear fashion. For the vapour pressure deficit function $f(\Delta e)$, two alternate forms are provided, after Oren et al. (1999) and Wu et al. (2000) respectively:

$$f(\Delta e) = [(\Delta e / 10.0)^{c_{v2}}] / c_{v1} \text{ and } f(\Delta e) = 1 / [\exp(-c_{v1} \Delta e / 10.0)]$$

where c_{v1} and c_{v2} are parameters depending on the vegetation category. If c_{v2} is greater than zero, the first form is used; if not, the second form is used. The soil moisture suction function $f(\Psi_s)$ is expressed, following Choudhury and Idso (1985) [**Choudhury1985-mm**] and Fisher et al. (1981) [**Fisher1981-xf**], as:

$$f(\Psi_s) = 1 + (\Psi_s / c_{\Psi 1})^{c_{\Psi 2}}$$

where $c_{\Psi 1}$ and $c_{\Psi 2}$ are parameters depending on the vegetation category. Finally, the aggregated stomatal resistance for the canopy over the bare ground subarea is obtained as a weighted average over the vegetation categories. (It is assumed that transpiration is suppressed when snow is present under the canopy, so r_c for this subarea is set to a large number). Since, following the electrical analogy, resistances act in parallel, the aggregated resistance for the subarea of canopy over bare ground is obtained as an average of inverses:

$$X / r_c = \Sigma (X_i / r_{c,i})$$

The calculations described above pertaining to stomatal resistances are performed in loops 850, 900 and 950. In the 850 loop, $f(T_a)$ is evaluated. In the 900 loop, for each vegetation category in turn, $f(\Delta e)$, $f(\Psi_s)$ and $r_{c,i}$ are determined. $r_{c,i}$ is assigned upper and lower limits of 5000 and 10 sm^{-1} respectively, and the accumulated stomatal resistance for the canopy is incremented by $X_i / r_{c,i}$. In loop 950, if the incoming visible radiation is small, the stomatal resistances are likewise set to a large number. Otherwise, the stomatal resistance of vegetation over snow is set to a large number, and the normalized, aggregated stomatal resistance of vegetation over soil is obtained by inverting the accumulated value.

Parameters

<i>thliq</i>	Volumetric liquid water content of soil
<i>tbar</i>	Temperature of soil layer $[K](T_g)$
<i>qfc</i>	Transpired water removed from soil layer $[kgm^{-2}s^{-1}]$
<i>htc</i>	Internal energy change of soil layer due to conduction and/or change in mass $[Wm^{-2}](I_g)$
<i>evap</i>	Evapotranspiration rate from vegetation canopy $[ms^{-1}]$
<i>subl</i>	Calculated sublimation rate from vegetation canopy $[ms^{-1}]$
<i>raican</i>	Intercepted liquid water stored on the canopy $[kgm^{-2}]$
<i>snocan</i>	Intercepted frozen water stored on the canopy $[kgm^{-2}]$
<i>tcn</i>	Temperature of vegetation canopy $[K](T_c)$
<i>zsnw</i>	Depth of snow pack $[m](z_g)$
<i>wlost</i>	Residual amount of water that cannot be supplied by surface stores $[kgm^{-2}]$
<i>chcap</i>	Heat capacity of vegetation canopy $[Jm^{-2}K^{-1}](C_c)$
<i>qfcf</i>	Sublimation from frozen water in canopy interception store $[kgm^{-2}s^{-1}]$
<i>qfcl</i>	Evaporation from liquid water in canopy interception store $[kgm^{-2}s^{-1}]$
<i>qfn</i>	Sublimation from snow pack $[kgm^{-2}s^{-1}]$
<i>htcc</i>	Internal energy change of canopy due to changes in temperature and/or mass $[Wm^{-2}](I_c)$
<i>htcs</i>	Internal energy change of snow pack due to conduction and/or change in mass $[Wm^{-2}](I_s)$
<i>froot</i>	Fractional contribution of soil layer to transpiration []
<i>thpor</i>	Pore volume in soil layer $[m^3m^{-3}]$
<i>thlmin</i>	Residual soil liquid water content remaining after freezing or evaporation $[m^3m^{-3}]$
<i>delzw</i>	Permeable depth of soil layer $[m](\Delta z_{g,w})$
<i>fi</i>	Fractional coverage of subarea in question on modelled area [] (X_i)
<i>cmass</i>	Mass of vegetation canopy $[kgm^{-2}]$

<i>tsnow</i>	Temperature of the snow pack [C]
<i>hcpsno</i>	Heat capacity of snow pack [$Jm^{-3}K^{-1}$](C_s)
<i>rhosno</i>	Density of snow pack [kgm^{-3}]

The calculated fluxes of liquid and frozen water from the canopy to the overlying air, obtained as outputs of WPREP, are applied to the liquid and frozen intercepted water stores on the vegetation canopy, and to the liquid and frozen moisture stores at the surface and in the soil. Since there may not be sufficient water in one or more of these stores to sustain the calculated rate over the whole time step, a hierarchy of operations is followed as described below. The change of internal energy HTC in the canopy, snow and soil layers as a result of these processes is calculated as the difference in HTC between the beginning and end of the subroutine:

$$\Delta I_c = X_i \Delta(C_c T_c) / \Delta t$$

$$\Delta I_s = X_i \Delta(C_s T_s z_s) / \Delta t$$

where the C terms represent volumetric heat capacities and the T terms temperatures of the canopy and snow pack, Δt is the length of the time step, z_s the snow depth, and X_i the fractional coverage of the subarea under consideration relative to the modelled area. For the soil layers, since only the liquid water content is affected by these calculations, the change in internal energy of each layer is calculated from the change in liquid water content θ_l as:

$$\Delta I_g = X_i C_w \Delta z_{g,w} \Delta(T_g \theta_l) / \Delta t$$

Sublimation is addressed first. The predicted mass of sublimated water SLOST is calculated and compared to the frozen water in the canopy interception store, SNOCAN. If $SLOST \leq SNOCAN$, all of the sublimated water is subtracted from SNOCAN. If not, the excess sublimation is calculated as $SLOST - SNOCAN$, QFCF is corrected for the canopy sublimation difference, and SNOCAN is set to zero. Next, the new value of SLOST is compared to the snowpack mass, calculated as $ZSNOW * RHOSNO$. If $SLOST \leq ZSNOW * RHOSNO$, all of the remaining sublimated water is taken from the snow pack, and QFN is modified to reflect this loss. Otherwise, the excess sublimation is calculated as $SLOST - ZSNOW * RHOSNO$, QFN is adjusted accordingly, and ZSNOW is set to zero. There now remain no further frozen moisture stores from which sublimated water can be taken (frozen water in the soil is assumed to be immobile), so the remaining energy that had been assigned to sublimation is assigned to canopy evaporation instead, and QFCL is duly recalculated. This means, however, that a small imbalance will arise in the water budget owing to the difference between the latent heats of sublimation and evaporation. This imbalance is assigned to the housekeeping variable WLOST.

Now canopy evaporation is addressed. It is assumed that all intercepted liquid water evaporates before transpiration begins, since there is a canopy stomatal resistance associated with transpiration and there is none associated with evaporation. The predicted mass of evaporated water RLOST is calculated and compared to the liquid water in the canopy interception store, RAICAN. If $RLOST \leq RAICAN$, all of the evaporated water is subtracted from RAICAN. If not, the excess evaporation is calculated as $RLOST - RAICAN$, and QFCL is corrected for the canopy evaporation difference. This excess evaporation is now treated as transpiration. An initial check is done by referring to the diagnostic flag IROOT, which was set to 1 at the beginning of the subroutine if there was water available for transpiration in any of the soil layers. If IROOT is zero, no transpiration can occur and the excess evaporation is stored in the temporary variable EVLOST.

6.8 src/CGROW.f File Reference

Purpose: Evaluate growth index used in calculating vegetation parameters for forests.

Functions/Subroutines

- subroutine [cgrow](#) (GROWTH, TBAR, TA, FC, FCS, ILG, IG, IL1, IL2, JL)

6.8.1 Detailed Description

Purpose: Evaluate growth index used in calculating vegetation parameters for forests.

6.8.2 Function/Subroutine Documentation

6.8.2.1 subroutine *cgrow* (real, dimension(ilg) *GROWTH*, real, dimension (ilg,ig) *TBAR*, real, dimension(ilg) *TA*, real, dimension(ilg) *FC*, real, dimension(ilg) *FCS*, integer *ILG*, integer *IG*, integer *IL1*, integer *IL2*, integer *JL*)

Parameters

<i>growth</i>	Tree growth index []
<i>tbar</i>	Temperature of soil layers [K]
<i>ta</i>	Air temperature [K]
<i>fc</i>	Fractional coverage of vegetation without snow on modelled area []
<i>fcs</i>	Fractional coverage of vegetation with underlying snow pack on modelled area []

The growth index that is calculated here varies from a value of 1 for periods when the trees are mature and fully leaved, to 0 for dormant and leafless periods, with a linear transition between the two. The transition periods are assumed to last for sixty days; therefore during these periods the growth index is incremented by $\Delta t / 5.184 \times 10^6$ where Δt is the time step in seconds.

The transition period from dormant to fully leaved is triggered when both the air temperature and the temperature of the first soil layer are above 2 C. If one of these conditions is not met afterwards, the growth index is reset back to 0. Increments are added continuously thereafter until the index reaches 1.

The transition from fully leaved to dormant is triggered when either the air temperature or the temperature of the first soil layer falls below 2 C. When this first happens at the end of the fully-leaved period, the growth index is set instantaneously to -1 and increments are continuously added from that point until the index reaches 0.

The absolute value of this growth index is utilized for performing calculations of various forest vegetation parameters in subroutine APREP; thus its shape as used there is that of a symmetrical trapezoidal function.

Parameters

<i>pcpr</i>	Precipitation rate over modelled subarea [$kgm^{-2}s^{-1}$]
<i>evap</i>	Evapotranspiration rate over modelled subarea [$kgm^{-2}s^{-1}$]
<i>runoff</i>	Total runoff over modelled subarea [m]
<i>wlost</i>	Residual amount of water that cannot be supplied by surface stores [kgm^{-2}]
<i>raican</i>	Intercepted liquid water on canopy at end of time step [kgm^{-2}]
<i>snocan</i>	Intercepted frozen water on canopy at end of time step [kgm^{-2}]
<i>raicni</i>	Intercepted liquid water on canopy at beginning of time step [kgm^{-2}]
<i>snocni</i>	Intercepted frozen water on canopy at beginning of time step [kgm^{-2}]
<i>zpond</i>	Depth of ponded water on ground at end of time step [m]
<i>zpondi</i>	Depth of ponded water on ground at beginning of time step [m]
<i>zsnow</i>	Depth of snow pack [m]
<i>rhosno</i>	Density of snow pack [kgm^{-3}]
<i>xsnow</i>	Switch to indicate presence of snow cover []
<i>snowi</i>	Snow pack mass at beginning of time step [kgm^{-2}]
<i>wsnow</i>	Liquid water content of snow pack at end of time step [kgm^{-2}]
<i>wsnowi</i>	Liquid water content of snow pack at beginning of time step [kgm^{-2}]
<i>fcs</i>	Fractional coverage of canopy over snow on modelled area []
<i>fgs</i>	Fractional coverage of snow over bare ground on modelled area []
<i>fi</i>	Fractional coverage of subarea in question on modelled area []
<i>thliq</i>	Volumetric liquid water content of soil layers at end of time step [m^3m^{-3}]
<i>thice</i>	Volumetric frozen water content of soil layers at end of time step [m^3m^{-3}]
<i>thliqi</i>	Volumetric frozen water content of soil layers at beginning of time step [m^3m^{-3}]
<i>thicei</i>	Volumetric frozen water content of soil layers at beginning of time step [m^3m^{-3}]
<i>thpor</i>	Pore volume in soil layer [m^3m^{-3}]
<i>thlmin</i>	Residual soil liquid water content remaining after freezing or evaporation [m^3m^{-3}]
<i>delzw</i>	Permeable depth of soil layer [m]

This subroutine is called from CLASSW to perform water balance checks for each of the four subareas. The flag ISFC indicates which subarea is being addressed: ISFC=1 for vegetation over snow, ISFC=2 for snow over bare ground, ISFC=3 for vegetation over bare ground, and ISFC=4 for bare ground. If a problem is discovered, a flag is set to the index of the modelled area, and a call to XIT is performed with an error message. Checks for unphysical values of certain water balance variables are performed against an accuracy limit ACCLMT, currently set to $1 \times 10^{-3} kgm^{-2}$ or m^3m^{-3} . The overall water balance of the subarea is checked against an accuracy limit BALLMT, currently set to $1 \times 10^{-1} kgm^{-2}$. (These values reflect expected roundoff errors associated with 32-bit computation.)

In loop 100, for canopy-covered subareas, the intercepted rain RAICAN and snow SNOCAN are checked to ensure that if they are negative, they are vanishingly small. A similar check is done for the runoff.

In the 150 loop, for all areas that are not continental ice sheets (ISAND=-4), the liquid water content in each soil layer is checked to ensure that it is not larger than the pore volume and that it is not smaller than the minimum liquid water content (except for rock layers). The ice content is similarly checked to ensure that the sum of it, converted to an equivalent liquid water content, plus the minimum water content, is not greater than the pore volume (except for rock layers). It is also checked to ensure that if it is negative, it is vanishingly small.

Finally, in loop 300, the overall water balance BAL is calculated and compared to BALLMT. BAL is evaluated as the residual of the precipitation, the evaporation, the runoff, the water loss term WLOST, the change in canopy intercepted liquid and frozen water (for vegetation-covered areas), the change in surface ponded water, the change in snow pack and snow liquid water content (for snow-covered areas), and the changes in the soil layer liquid and frozen water contents. If the absolute value of BAL is greater than BALLMT, a flag is set, all of the terms entering BAL are printed out, and a call to XIT is performed.

CLASS's monthly outputs.

Functions/Subroutines

- subroutine, public `class_statevars::alloc_class_vars` ()
- subroutine, public `class_statevars::resetclassmon` (nltest)
- subroutine, public `class_statevars::resetclassyr` (nltest)
- subroutine, public `class_statevars::resetclassaccum` (nltest, nmtest)

Variables

- type(`class_gather`), target, save `class_statevars::class_gat`
- type(`class_rotated`), target, save `class_statevars::class_rot`
- type(`class_moyr_output`), target, save `class_statevars::class_out`

6.10.1 Detailed Description

this module contains the variable type structures:

1. `class_rot` - CLASS's 'rot' and 'row' vars
2. `class_gat` - CLASS's 'gat' vars
3. `class_out` - CLASS's monthly outputs

6.11 src/CLASSA.f File Reference

Purpose: Organize calculation of radiation-related and other surface parameters.

<i>coszs</i>	Cosine of solar zenith angle []
<i>qswinv</i>	Visible radiation incident on horizontal surface [$W m^{-2}$]
<i>dlon</i>	Longitude of grid cell (east of Greenwich) [degrees]
<i>zblend</i>	Atmospheric blending height for surface roughness length averaging [m]
<i>snolim</i>	Limiting snow depth below which coverage is < 100% [m]($z_{s,lim}$)
<i>zplmg0</i>	Maximum water ponding depth for snow-free subareas (user-specified when running MESH code) [m]
<i>zplms0</i>	Maximum water ponding depth for snow-covered subareas (user-specified when running MESH code) [m]
<i>radj</i>	Latitude of grid cell (positive north of equator) [rad]
<i>refsno</i>	Snow grain size (for ISNOALB=1 option) [m]
<i>bcsno</i>	Black carbon mixing ratio (for ISNOALB=1 option) [$kg m^{-3}$]
<i>fsdb</i>	Direct solar radiation in each modelled wavelength band [$W m^{-2}$]
<i>fsfb</i>	Diffuse solar radiation in each modelled wavelength band [$W m^{-2}$]
<i>delzw</i>	Permeable thickness of soil layer [m]

<i>zbotw</i>	Depth to permeable bottom of soil layer [m]
<i>thpor</i>	Pore volume in soil layer [m^3m^{-3}]
<i>thlmin</i>	Residual soil liquid water content remaining after freezing or evaporation [m^3m^{-3}]
<i>psisat</i>	Soil moisture suction at saturation [m]
<i>bi</i>	Clapp and Hornberger empirical "b" parameter []
<i>psiwlt</i>	Soil moisture suction at wilting point [m]
<i>hcps</i>	Volumetric heat capacity of soil particles [Jm^{-3}]
<i>isand</i>	Sand content flag
<i>delz</i>	Soil layer thickness [m]
<i>ipeatland</i>	Peatland flag: 0 = not a peatland, 1 = bog, 2 = fen

In the first loop, the depth of snow z_s is calculated from the snow mass W_s and density ρ_s as: $z_s = W_s / \rho_s$.

If the calculated value of z_s is less than the limiting snow depth $z_{s,lim}$, the snow cover is deemed to be discontinuous. The fractional snow coverage X_s of the modelled area is evaluated as $X_s = z_s / z_{s,lim}$ and the snow depth is reset to $z_{s,lim}$. The water content of the snow pack is corrected according to the new snow fractional area.

The subarea albedo and transmissivity arrays (for canopy, bare ground, canopy over snow and snow over bare ground) are next initialized to zero, and the four CLASSA subsidiary subroutines are called in turn: APREP to evaluate various model parameters for the four subareas, GRALB to calculate the ground surface albedo, SNOALBA to calculate the snow albedo and transmissivity, and CANALB to calculate the canopy albedo, transmissivity and stomatal resistance. Finally, the overall visible, near-infrared and total albedos for the modelled area are determined as weighted averages over the four subareas.

6.12 src/CLASSB.f File Reference

Purpose: Assign thermal and hydraulic properties to soil layers based on sand/clay content, or soil type. Also calculate permeable thickness of soil layers, and wet and dry surface albedo for mineral soils.

Functions/Subroutines

- subroutine [classb](#) (THPOR, THLRET, THLMIN, BI, PSISAT, GRKSAT, THLRAT, HCPS, TCS, THFC, THLW, PSIWLT, DELZW, ZBOTW, ALGWV, ALGWN, ALGDV, ALGDN, SAND, CLAY, ORGM, SOCI, DELZ, ZBOT, SDEPTH, ISAND, IGDR, NL, NM, IL1, IL2, IM, IG, ipeatland)

6.12.1 Detailed Description

Purpose: Assign thermal and hydraulic properties to soil layers based on sand/clay content, or soil type. Also calculate permeable thickness of soil layers, and wet and dry surface albedo for mineral soils.

<i>zbotw</i>	Depth of bottom of permeable part of soil layer [m]
<i>algwv</i>	Visible albedo of wet soil for modelled area []
<i>algwn</i>	NIR albedo of wet soil for modelled area []
<i>algdv</i>	Visible albedo of dry soil for modelled area []
<i>algdn</i>	NIR albedo of dry soil for modelled area []
<i>isand</i>	Sand content flag
<i>igdr</i>	Index of soil layer in which bedrock is encountered
<i>ipeatland</i>	Peatland flag: 0 = not a peatland, 1 = bog, 2 = fen
<i>sand</i>	Percent sand content of soil layer [percent] (X_{sand})
<i>clay</i>	Percent clay content of soil layer [percent] (X_{clay})
<i>orgm</i>	Percent organic matter content of soil layer [percent]
<i>delz</i>	Thickness of soil layer [m]
<i>zbot</i>	Depth of bottom of soil layer [m]
<i>sdepth</i>	Permeable depth of soil column (depth to bedrock) [m] (z_b)
<i>soci</i>	Soil colour index

In the first section of code, two integer flags are evaluated: IGDR, the index of the soil layer in which the bottom of the soil permeable depth, z_b , occurs; and ISAND, the value of the SAND variable for each soil layer converted to an integer. ISAND is used throughout the CLASS code as a flag to determine which branches of code to execute.

In loop 200, calculations are done to determine the permeable thickness DELZW of each soil layer. If the land cover is an ice sheet (indicated by an ISAND value of -4 in the top layer), the value of DELZW in each layer is set to DELZ, the standard thickness of the corresponding thermal layer, and the soil flag is set to -4. If the layer consists of rock, indicated by an ISAND value of -3, DELZW is set to 0. For soil layers where z_b occurs below the bottom of the layer, DELZW is set to DELZ; for layers where z_b occurs near the top of the layer, DELZW is set to 0 and ISAND is set to -3. For the soil layer containing z_b , DELZW is set to the distance from the top of the layer to z_b , and is further constrained to be ≥ 5 cm, to avoid overshoots in the water movement calculations. For all layers, the distance to the bottom of its respective permeable depth, ZBOTW, is set to the depth of the top of the layer plus DELZW. At the end of the loop, if the soil is a mineral one, the wet and dry albedo values are calculated using simple empirical functions derived from values given in Wilson and Henderson-Sellers (1985). (The dry albedo calculation varies slightly depending on whether or not CTEM is being run.)

In loop 300, various thermal and hydraulic soil properties are assigned to each of the soil layers, depending on soil type. Values of ISAND greater than zero indicate mineral soil. The pore volume θ_p , the saturated hydraulic conductivity K_{sat} , and the soil moisture suction at saturation Ψ_{sat} are calculated from the percentage sand content X_{sand} , and the hydraulic parameter b is calculated from the percentage clay content X_{clay} , based on empirical relationships given in Cosby et al. (1984) **[Cosby1984-jc:]** $\theta_p = (-0.126X_{sand} + 48.9)/100.0$ $b = 0.159X_{clay} + 2.91$ $\Psi_{sat} = 0.01exp(-0.0302X_{sand} + 4.33)$ $K_{sat} = 7.0556 \times 10^{-6}exp(0.0352X_{sand} - 2.035)$

The fractional saturation of the soil at half the saturated hydraulic conductivity, f_{inf} , is calculated by inverting the Clapp and Hornberger (1978) **[Clapp1978-898]** expression relating hydraulic conductivity K to liquid water content of the soil θ_l : $K = K_{sat}(\theta_l/\theta_p)(2b + 3)$

Thus, $f_{inf} = 0.51/(2b + 3)$

The residual soil liquid water content remaining after evaporation or freezing, θ_{min} , and the liquid water retention

capacity, θ_{ret} , are both set for mineral soils to a textbook value of 0.04. The volumetric sand, silt + clay and organic matter components of the soil matrix are derived by converting the percent values to volume fractions. The overall volumetric heat capacity of the soil material, C_g , is then calculated as a weighted average: $C_g = \Sigma(C_{sand}\theta_{sand} + C_{fine}\theta_{fine} + C_{org}\theta_{org})/(1 - \theta_p)$ where the subscript "fine" refers to the silt and clay particles taken together. The thermal conductivity of the soil material, τ_g , is likewise calculated as a weighted average over the thermal conductivities of the components: $\tau_g = \Sigma(\tau_{sand}\theta_{sand} + \tau_{fine}\theta_{fine} + \tau_{org}\theta_{org})/(1 - \theta_p)$

The field capacity θ_{fc} , that is, the liquid water content of the soil at which gravitational drainage effectively ceases, is calculated by setting the expression for K above to a value of 0.1 mm d^{-1} , and solving for the liquid water content: $\theta_{fc} = \theta_p(1.157 \times 10^{-9}/K_{sat})^{1/(2b+3)}$

The only exception is the field capacity of the lowest permeable layer in mineral soils (layer IGDR), which is determined using an expression developed by Soulis et al. (2010), which takes into account the permeable depth of the whole overlying soil: $\theta_{fc} = \theta_p/(b-1) \bullet (\Psi_{sat}b/z_b)^{1/b} \bullet [(3b+2)^{(b-1)/b} - (2b+2)^{(b-1)/b}]$

The soil moisture suction Ψ_{wilt} at the wilting point (the liquid water content at which plant roots can no longer draw water from the soil) is assigned a textbook value of 150.0 m. The liquid water content at the wilting point, θ_{wilt} , is determined from Ψ_{wilt} by inverting the calculated from the saturated soil moisture suction using the Clapp and Hornberger (1978) [Clapp1978-898] expression for soil moisture suction as a function of liquid water content: $\theta_{wilt} = \theta_p(\theta_{wilt}/\Psi_{sat})^{-1/b}$

Organic soils are flagged with an ISAND value of -2. For these soils, the variables θ_p , b , K_{sat} , Ψ_{sat} , θ_{min} , and θ_{ret} are assigned values based on the peat texture (fibric, hemic or sapric). These values are obtained from the arrays in common block CLASS5 (see the CLASSBD documentation above). The current default is to assume the first soil layer as fibric, the second as hemic, and any lower layers as sapric. The volumetric heat capacity and thermal conductivity are set to textbook values for organic matter; the field capacity is set equal to the retention capacity; f_{inf} is obtained as above; and Ψ_{wilt} is assume to apply at a liquid water content of θ_{min} .

In the cases of rock soils and ice sheets (respectively flagged with ISAND values of -3 and -4), all of the above variables are set to zero except for the volumetric heat capacity and the thermal conductivity, which are assigned values representative of rock or ice.

Purpose: Assign values to parameters in CLASS common blocks. CLASS incorporates several kinds of parameters in its common blocks. Some are defined specifically for use in the CLASS code; some are also shared with the atmospheric model (if running in coupled mode).

6.13.1 Detailed Description

Purpose: Assign values to parameters in CLASS common blocks. CLASS incorporates several kinds of parameters in its common blocks. Some are defined specifically for use in the CLASS code; some are also shared with the atmospheric model (if running in coupled mode).

In routine CLASSBD, values are primarily assigned to the parameters that are specific to the CLASS code and are passed through it via common blocks CLASS1 through CLASS8. The table below lists the scalar parameters, their

definitions, and their designated values with units.

Name	Definition	Value	Units
VKC	Von Karman Constant	0.40	-
CT	Drag Coefficient for water	1.1510^{-3}	-
VMIN	Minimum wind speed	0.1	ms^{-1}
TCW	Thermal conductivity of water	0.57	$Wm^{-1}K^{-1}$
TCICE	Thermal conductivity of ice	2.24	$Wm^{-1}K^{-1}$
TCSAND	Thermal conductivity of sand particles	2.5	$Wm^{-1}K^{-1}$
TCCLAY	Thermal conductivity of fine mineral particles	2.5	$Wm^{-1}K^{-1}$
TCOM	Thermal conductivity of organic matter	0.25	$Wm^{-1}K^{-1}$
TCDRYS	Thermal conductivity of dry mineral soil	0.275	$Wm^{-1}K^{-1}$
RHOSOL	Density of soil mineral matter	2.6510^3	kgm^{-3}
RHOOM	Density of soil organic matter	1.3010^3	kgm^{-3}
HCPW	Volumetric heat capacity of water	4.18710^6	$Jm^{-3}K^{-1}$
HCPICE	Volumetric heat capacity of ice	1.925710^6	$Jm^{-3}K^{-1}$
HCPSOL	Volumetric heat capacity of mineral matter	2.2510^6	$Jm^{-3}K^{-1}$
HCPOM	Volumetric heat capacity of organic matter	2.5010^6	$Jm^{-3}K^{-1}$
HCPSND	Volumetric heat capacity of sand particles	2.1310^6	$Jm^{-3}K^{-1}$
HCPCLY	Volumetric heat capacity of fine mineral particles	2.3810^6	$Jm^{-3}K^{-1}$
SPHW	Specific heat of water	4.18610^3	$Jkg^{-1}K^{-1}$
SPHICE	Specific heat of ice	2.1010^3	$Jkg^{-1}K^{-1}$
SPHVEG	Specific heat of vegetation matter	2.7010^3	$Jkg^{-1}K^{-1}$
RHOW	Density of water	1.010^3	kgm^{-3}
RHOICE	Density of ice	0.91710^3	kgm^{-3}
TCGLAC	Thermal conductivity of ice sheets	2.24	$Wm^{-1}K^{-1}$
CLHMLT	Latent heat of freezing of water	0.33410^6	Jkg^{-1}
CLHVAP	Latent heat of vaporization of water	2.50110^6	Jkg^{-1}
ZOLNG	Natural log of roughness length of soil	-4.605	-
ZOLNS	Natural log of roughness length of snow	-6.908	-
ZOLNI	Natural log of roughness length of ice	-6.215	-
ZORATG	Ratio of soil roughness length for momentum to roughness length for heat	3.0	-
ALVSI	Visible albedo of ice	0.95	-
ALIRI	Near-infrared albedo of ice	0.73	-
ALVSO	Visible albedo of organic matter	0.05	-
ALIRO	Near-infrared albedo of organic matter	0.30	-
ALBRCK	Albedo of rock	0.27	-

Values are also assigned to several non-scalar parameters, as follows:

- 1) The crop growth descriptor array GROWYR (see the documentation for subroutine APREP);
- 2) Three parameters for the four main vegetation categories recognized by CLASS (needleleaf trees, broadleaf trees, crops and grass): ZORAT, the ratio of the roughness length for momentum to the roughness length for heat (currently set to 1); CANEXT, an attenuation coefficient used in calculating the sky view factor for vegetation canopies (variable c in the documentation for subroutine CANALB); and XLEAF, a leaf dimension factor used in calculating the leaf boundary resistance (variable Cl in the documentation for subroutine APREP);
- 3) Six hydraulic parameters associated with the three basic types of organic soils (fibric, hemic and sapric): THP↔ORG, THROrg, THMORG, BORG, PSISORG and GRKSORG (see the documentation for subroutine CLASSB). The table below lists their values, derived from the work of Letts et al. (2000), alongside the symbols used in the CLASSB documentation.

Name	Symbol	Fibric peat	Hemic peat	Sapric peat
THPORG	θ_p	0.93	0.88	0.83
BORG	b	2.7	6.1	12.0
GRKSORG	K_{sat}	2.810^{-4}	2.010^{-6}	1.010^{-7}
PSISORG	psi_{sat}	0.0103	0.0102	0.0101
THMORG	$theta_{min}$	0.04	0.15	0.22
THRORG	$theta_{ret}$	0.275	0.62	0.705

Finally, if CLASS is being run offline, values must be assigned to the parameters listed in the first table which would normally be assigned in the GCM:

GCM Name	Definition	Value	Units
DELTIM	Time Step	Varies by run	s
CELZRO	Freezing point of water	273.16	K
GAS	Gas constant	287.04	$Jkg^{-1}K^{-1}$
GASV	Gas constant for water vapour	461.50	$Jkg^{-1}K^{-1}$
G	Acceleration due to gravity	9.80616	ms^{-1}
SIGMA	Stefan-Boltzmann constant	5.6679610^{-8}	$Wm^{-2}K^{-4}$
CPRES	Specific heat of air	1.0046410^3	$Jkg^{-1}K^{-1}$
CPI	Pi	3.14159265	-

The parameters in common blocks PHYCON and CLASSD2 that do not have corresponding values assigned in the GCM are assigned their RPN values, and the remaining parameters in the GCM common blocks PARAMS, PARAM1, PARAM3 and TIMES are assigned dummy values.

6.14 src/CLASSD.f File Reference

Purpose: Assign values to parameters in CLASS common blocks. CLASS incorporates several kinds of parameters in its common blocks. Some are defined specifically for use in the CLASS code; some are also shared with the atmospheric model (if running in coupled mode).

Functions/Subroutines

- subroutine **classd**

6.14.1 Detailed Description

Purpose: Assign values to parameters in CLASS common blocks. CLASS incorporates several kinds of parameters in its common blocks. Some are defined specifically for use in the CLASS code; some are also shared with the atmospheric model (if running in coupled mode).

In subroutine CLASSD, for consistency throughout the code, some parameters in the CLASS common blocks are set equal to their corresponding values in the common blocks PARAMS, PARAM1, PARAM3 and TIMES from the CGCM. Also, some parameters in the common block PHYCON which is used in the RPN subroutines DIASURFZ and FLXSURFZ are set equal to their values defined in the CGCM or in the block data routine CLASSBD. The parameters in question are as follows:

CLASS/RPN name	GCM name	Definition	Units
DELT	DELTIM	Time step	s
TFREZ	CELZRO	Freezing point of water	K
RGAS	GAS	Gas constant	$Jkg^{-1}K^{-1}$
RGASV	GASV	Gas constant for water vapour	$Jkg^{-1}K^{-1}$
GRAV	G	Acceleration due to gravity	ms^{-1}
CGRAV	G	Acceleration due to gravity	ms^{-1}
SBC	SIGMA	Stefan-Boltzmann constant	$Wm^{-2}K^{-4}$
CKARM	VKC	Von Karman constant	-
SPHAIR	CPRES	Specific heat of air	$Jkg^{-1}K^{-1}$
CPD	CPRES	Specific heat of air	$Jkg^{-1}K^{-1}$
PI	CPI	Pi	-

6.15.1 Detailed Description

Purpose: Gather variables from two-dimensional arrays (latitude circle x mosaic tiles) onto long vectors for optimum processing efficiency on vector supercomputers.

6.15.2 Function/Subroutine Documentation

Parameters

<i>tbarrot</i>	Temperature of soil layers [K]
<i>thlqrot</i>	Volumetric liquid water content of soil layers [m^3m^{-3}]
<i>thicrot</i>	Frozen water content of soil layers under vegetation [m^3m^{-3}]
<i>tpndrot</i>	Temperature of ponded water [K]
<i>zpndrot</i>	Depth of ponded water on surface [m]
<i>tbasrot</i>	Temperature of bedrock in third soil layer [K]
<i>albsrot</i>	Snow albedo []
<i>tsnorot</i>	Snowpack temperature [K]
<i>rhosrot</i>	Density of snow [kgm^{-3}]
<i>snorot</i>	Mass of snow pack [kgm^{-2}]
<i>tcanrot</i>	Vegetation canopy temperature [K]
<i>rcanrot</i>	Intercepted liquid water stored on canopy [kgm^{-2}]
<i>scanrot</i>	Intercepted frozen water stored on canopy [kgm^{-2}]
<i>grorot</i>	Vegetation growth index []
<i>cmairrot</i>	Aggregated mass of vegetation canopy [kgm^{-2}]
<i>tsfsrot</i>	Ground surface temperature over subarea [K]
<i>tacrot</i>	Temperature of air within vegetation canopy [K]
<i>qacrot</i>	Specific humidity of air within vegetation canopy [$kgkg^{-1}$]
<i>wsnorot</i>	Liquid water content of snow pack [kgm^{-2}]
<i>ilmos</i>	Index of latitude grid cell corresponding to current element of gathered vector of land surface variables []
<i>jmos</i>	Index of mosaic tile corresponding to current element of gathered vector of land surface variables []
<i>fcanrot</i>	Maximum fractional coverage of modelled area by vegetation category []
<i>lnz0rot</i>	Natural logarithm of maximum roughness length of vegetation category []
<i>alvcrot</i>	Background average visible albedo of vegetation category []
<i>alicrot</i>	Background average near-infrared albedo of vegetation category []
<i>pamxrot</i>	Maximum plant area index of vegetation category []
<i>pamnrot</i>	Minimum plant area index of vegetation category []
<i>cmasrot</i>	Maximum canopy mass for vegetation category [kgm^{-2}]
<i>rootrot</i>	Maximum rooting depth of vegetation category [m]
<i>rsmnrot</i>	Minimum stomatal resistance of vegetation category [sm^{-1}]
<i>qa50rot</i>	Reference value of incoming shortwave radiation for vegetation category (used in stomatal resistance calculation) [Wm^{-2}]
<i>vpdarot</i>	Vapour pressure deficit coefficient for vegetation category (used in stomatal resistance calculation) []
<i>vpdbrot</i>	Vapour pressure deficit coefficient for vegetation category (used in stomatal resistance calculation) []
<i>psgarot</i>	Soil moisture suction coefficient for vegetation category (used in stomatal resistance calculation) []
<i>psgbrot</i>	Soil moisture suction coefficient for vegetation category (used in stomatal resistance calculation) []
<i>paidrot</i>	Optional user-specified value of plant area indices of vegetation categories to override CLASS-calculated values []
<i>hgtrot</i>	Optional user-specified values of height of vegetation categories to override CLASS-calculated values [m]

<i>acvdrot</i>	Optional user-specified value of canopy visible albedo to override CLASS- calculated value []
<i>acidrot</i>	Optional user-specified value of canopy near-infrared albedo to override CLASS- calculated value []
<i>thprot</i>	Pore volume in soil layer [m^3m^{-3}]
<i>thrtrot</i>	Liquid water retention capacity for organic soil [m^3m^{-3}]
<i>thmrot</i>	Residual soil liquid water content remaining after freezing or evaporation [m^3m^{-3}]
<i>birot</i>	Clapp and Hornberger empirical "b" parameter []
<i>psisrot</i>	Soil moisture suction at saturation [m]
<i>grksrot</i>	Saturated hydraulic conductivity of soil layers [ms^{-1}]
<i>thrarot</i>	Fractional saturation of soil behind the wetting front []
<i>hcpsrot</i>	Volumetric heat capacity of soil particles [Jm^{-3}]
<i>tcsrot</i>	Thermal conductivity of soil particles [$Wm^{-1}K^{-1}$]
<i>thfcrot</i>	Field capacity [m^3m^{-3}]
<i>thlwrot</i>	Wilting point [m^3m^{-3}]
<i>psiwrot</i>	Soil moisture suction at wilting point [m]
<i>dlzwrot</i>	Permeable thickness of soil layer [m]
<i>zbtwrot</i>	Depth to permeable bottom of soil layer [m]
<i>drnrot</i>	Drainage index at bottom of soil profile []
<i>xslprot</i>	Surface slope (used when running MESH code) [degrees]
<i>grkfstrot</i>	WATROF parameter used when running MESH code []
<i>wfsfstrot</i>	WATROF parameter used when running MESH code []
<i>wfcfstrot</i>	WATROF parameter used when running MESH code []
<i>asvdrot</i>	Optional user-specified value of snow visible albedo to override CLASS- calculated value []
<i>asidrot</i>	Optional user-specified value of snow near-infrared albedo to override CLASS- calculated value []
<i>agvdrot</i>	Optional user-specified value of ground visible albedo to override CLASS- calculated value []
<i>agidrot</i>	Optional user-specified value of ground near-infrared albedo to override CLASS- calculated value []
<i>zsnlrot</i>	Limiting snow depth below which coverage is < 100% [m]
<i>zplgrot</i>	Maximum water ponding depth for snow- free subareas (user-specified when running MESH code) [m]
<i>zplsrot</i>	Maximum water ponding depth for snow- covered subareas (user-specified when running MESH code) [m]
<i>isndgat</i>	Sand content flag
<i>igdrgat</i>	Index of soil layer in which bedrock is encountered
<i>zrfmrow</i>	Reference height associated with forcing wind speed [m]
<i>zrfhrow</i>	Reference height associated with forcing air temperature and humidity [m]
<i>zdmrow</i>	User-specified height associated with diagnosed anemometer-level wind speed [m]
<i>zdhrow</i>	User-specified height associated with diagnosed screen-level variables [m]
<i>fsvhrow</i>	Visible radiation incident on horizontal surface [Wm^{-2}]
<i>fsihrow</i>	Near-infrared radiation incident on horizontal surface [Wm^{-2}]
<i>cszrow</i>	Cosine of solar zenith angle []
<i>fdlrol</i>	Downwelling longwave radiation at bottom of atmosphere [Wm^{-2}]
<i>ulrow</i>	Zonal component of wind speed [ms^{-1}]
<i>vlrow</i>	Meridional component of wind speed [ms^{-1}]
<i>tarow</i>	Air temperature at reference height [K]
<i>qarow</i>	Specific humidity at reference height [$kgkg^{-1}$]

<i>presrow</i>	Surface air pressure [Pa]
<i>prerow</i>	Surface precipitation rate [$kgm^{-2}s^{-1}$]
<i>padrow</i>	Partial pressure of dry air [Pa]
<i>vpdrow</i>	Vapour pressure deficit [mb]
<i>tadprow</i>	Dew point temperature of air [K]
<i>rhoarow</i>	Density of air [kgm^{-3}]
<i>zbldrow</i>	Atmospheric blending height for surface roughness length averaging [m]
<i>z0orow</i>	Orographic roughness length [m]
<i>rpcprow</i>	Rainfall rate over modelled area [ms^{-1}]
<i>trpcrow</i>	Rainfall temperature [K]
<i>spcprow</i>	Snowfall rate over modelled area [ms^{-1}]
<i>tspcrow</i>	Snowfall temperature [K]

<i>radj</i>	Latitude of grid cell (positive north of equator) [rad]
<i>vmodl</i>	Wind speed at reference height [ms^{-1}]

6.16 src/CLASSI.f File Reference

Purpose: Evaluate atmospheric variables and rainfall/snowfall rates over modelled area.

Functions/Subroutines

- subroutine [classi](#) (VPD, TADP, PADRY, RHOAIR, RHOSNI, RPCP, TRPCP, SPCP, TSPCP, TA, QA, PCPR, RRATE, SRATE, PRESSG, IPCP, NL, IL1, IL2)

6.16.1 Detailed Description

Purpose: Evaluate atmospheric variables and rainfall/snowfall rates over modelled area.

6.16.2 Function/Subroutine Documentation

- 6.16.2.1 subroutine `classi` (real, dimension (nl) *VPD*, real, dimension (nl) *TADP*, real, dimension (nl) *PADRY*, real, dimension (nl) *RHOAIR*, real, dimension (nl) *RHOSNI*, real, dimension (nl) *RPCP*, real, dimension (nl) *TRPCP*, real, dimension (nl) *SPCP*, real, dimension (nl) *TSPCP*, real, dimension (nl) *TA*, real, dimension (nl) *QA*, real, dimension (nl) *PCPR*, real, dimension (nl) *RRATE*, real, dimension (nl) *SRATE*, real, dimension (nl) *PRESSG*, integer *IPCP*, integer *NL*, integer *IL1*, integer *IL2*)

Parameters

<i>vpd</i>	Vapour pressure deficit of air [mb](e_d)
<i>tadp</i>	Dew point temperature of air [K]
<i>padry</i>	Partial pressure of dry air [Pa](p_{dry})
<i>rhoair</i>	Density of air [kgm^{-3}](ρ_a)
<i>rhosni</i>	Density of fresh snow [kgm^{-3}]($\rho_{s,i}$)
<i>rpcp</i>	Calculated rainfall rate over modelled area [ms^{-1}]

<i>trpcp</i>	Rainfall temperature over modelled area [C]
<i>spcp</i>	Calculated snowfall rate over modelled area [ms^{-1}]
<i>tspcp</i>	Snowfall temperature over modelled area [C]
<i>ta</i>	Air temperature at reference height [K] (T_a)
<i>qa</i>	Specific humidity at reference height [$kgkg^{-1}$] (q_a)
<i>pressg</i>	Surface atmospheric pressure [Pa] (p)
<i>pcpr</i>	Precipitation rate over modelled area [$kgm^{-2}s^{-1}$]
<i>rrate</i>	Input rainfall rate over modelled area [$kgm^{-2}s^{-1}$]
<i>srate</i>	Input snowfall rate over modelled area [$kgm^{-2}s^{-1}$]

In the first section, the air vapour pressure deficit, dry air pressure, air density and dew point temperature are calculated. The vapour pressure deficit e_d (in units of mb) is obtained from the saturated and actual vapour pressures of the air, e_a and $e_{a,sat}$ respectively (in units of Pa), as $e_d = [e_{a,sat} - e_a]/100.0$

The air vapour pressure is obtained from the specific humidity q_a using the formula

$$e_a = q_a p / [0.622 + 0.378 q_a]$$

where p is the surface atmospheric pressure. For the saturated vapour pressure, a standard empirical equation is utilized relating $e_{a,sat}$ to the temperature T_a and the freezing point T_f :

$$e_{a,sat} = 611.0 \exp[17.269 * (T_a - T_f) / (T_a + 35.86)] \quad T_a \geq T_f$$

$$e_{a,sat} = 611.0 \exp[21.874 (T_a - T_f) / (T_a + 7.66)] \quad T_a < T_f$$

The partial pressure of dry air, p_{dry} , is obtained by subtracting e_a from p , and the density of the air is calculated as the sum of the densities of the dry air and the water vapour: $\rho_a = p_{dry} / R_d T_a + e_a / R_v T_a$

where R_d and R_v are the gas constants for dry air and water vapour respectively. The dew point temperature of the air is evaluated by substituting e_a for $e_{a,sat}$ on the left-hand side of the appropriate equation above, and solving for T_a .

Finally, if $IPCP = 4$, this indicates that the partitioning between rainfall and snowfall has been done outside of CLASSIC. The rainfall and snowfall rates $RRATE$ and $SRATE$ that have been passed into the subroutine are therefore simply assigned to $RPCP$ and $SPCP$.

Purpose: Scatter variables from long, gathered vectors back onto original two-dimensional arrays (latitude circle x mosaic tiles).

6.18.2 Function/Subroutine Documentation

6.18.2.1 subroutine `classs` (real, dimension(nl,nt,ig) *TBARROT*, real, dimension(nl,nt,ig) *THLQROT*, real, dimension(nl,nt,ig) *THICROT*, real, dimension(nl,nt,4) *TSFSROT*, real, dimension(nl,nt) *TPNDROT*, real, dimension(nl,nt) *ZPNDROT*, real, dimension(nl,nt) *TBASROT*, real, dimension(nl,nm) *ALBSROT*, real, dimension(nl,nm) *TSNOROT*, real, dimension(nl,nm) *RHOSROT*, real, dimension(nl,nm) *SNOROT*, real, dimension(nl,nm) *GTROT*, real, dimension(nl,nt) *TCANROT*, real, dimension(nl,nt) *RCANROT*, real, dimension(nl,nt) *SCANROT*, real, dimension(nl,nt) *GROROT*, real, dimension(nl,nt) *CMAIROT*, real, dimension(nl,nt) *TACROT*, real, dimension(nl,nt) *QACROT*, real, dimension(nl,nm) *WSNOROT*, real, dimension(nl,nm) *REFROT*, real, dimension(nl,nm) *BCSNROT*, real, dimension(nl,nm) *EMISROT*, real, dimension(nl,nm,nbs) *SALBROT*, real, dimension(nl,nm,nbs) *CSALROT*, integer, dimension(ilg) *ILMOS*, integer, dimension(ilg) *JLMOS*, integer *NML*, integer *NL*, integer *NT*, integer *NM*, integer *ILG*, integer *IG*, integer *IC*, integer *ICP1*, integer *NBS*, real, dimension(ilg,ig) *TBARGAT*, real, dimension(ilg,ig) *THLQGAT*, real, dimension(ilg,ig) *THICGAT*, real, dimension(ilg,4) *TSFSGAT*, real, dimension(ilg) *TPNDGAT*, real, dimension(ilg) *ZPNDGAT*, real, dimension(ilg) *TBASGAT*, real, dimension(ilg) *ALBSGAT*, real, dimension(ilg) *TSNOGAT*, real, dimension(ilg) *RHOSGAT*, real, dimension(ilg) *SNOGAT*, real, dimension(ilg) *GTGAT*, real, dimension(ilg) *TCANGAT*, real, dimension(ilg) *RCANGAT*, real, dimension(ilg) *SCANGAT*, real, dimension(ilg) *GROGAT*, real, dimension(ilg) *CMAIGAT*, real, dimension(ilg) *TACGAT*, real, dimension(ilg) *QACGAT*, real, dimension(ilg) *WSNOGAT*, real, dimension(ilg) *REFGAT*, real, dimension(ilg) *BCSNGAT*, real, dimension(ilg) *EMISGAT*, real, dimension(ilg,nbs) *SALBGAT*, real, dimension(ilg,nbs) *CSALGAT*)

Parameters

<i>salbrot</i>	Suffix ROT refers to variables on original two-dimensional arrays.
<i>csalrot</i>	Suffix ROT refers to variables on original two-dimensional arrays.
<i>tbarrot</i>	Temperature of soil layers [K] Suffix ROT refers to variables on original two-dimensional arrays.
<i>thlqrot</i>	Volumetric liquid water content of soil layers $[m^3m^{-3}]$ Suffix ROT refers to variables on original two-dimensional arrays.
<i>thicrot</i>	Volumetric frozen water content of soil layers $[m^3m^{-3}]$ Suffix ROT refers to variables on original two-dimensional arrays.
<i>tsfsrot</i>	Ground surface temperature over subarea [K] Suffix ROT refers to variables on original two-dimensional arrays.
<i>tpndrot</i>	Temperature of ponded water [K] Suffix ROT refers to variables on original two-dimensional arrays.
<i>zpndrot</i>	Depth of ponded water on surface [m] Suffix ROT refers to variables on original two-dimensional arrays.

<i>tbasrot</i>	Temperature of bedrock in third soil layer [K] Suffix ROT refers to variables on original two-dimensional arrays.
<i>albsrot</i>	Snow albedo [] Suffix ROT refers to variables on original two-dimensional arrays.
<i>tsnorot</i>	Snowpack temperature [K] Suffix ROT refers to variables on original two-dimensional arrays.
<i>rhosrot</i>	Density of snow [kgm^{-3}] Suffix ROT refers to variables on original two-dimensional arrays.
<i>snorot</i>	Mass of snow pack [kgm^{-2}] Suffix ROT refers to variables on original two-dimensional arrays.
<i>gtrot</i>	Suffix ROT refers to variables on original two-dimensional arrays.
<i>tcanrot</i>	Vegetation canopy temperature [K] Suffix ROT refers to variables on original two-dimensional arrays.
<i>rcanrot</i>	Intercepted liquid water stored on canopy [kgm^{-2}] Suffix ROT refers to variables on original two-dimensional arrays.
<i>scanrot</i>	Intercepted frozen water stored on canopy [kgm^{-2}] Suffix ROT refers to variables on original two-dimensional arrays.
<i>grorot</i>	Vegetation growth index [] Suffix ROT refers to variables on original two-dimensional arrays.
<i>tacrot</i>	Temperature of air within vegetation canopy [K] Suffix ROT refers to variables on original two-dimensional arrays.
<i>qacrot</i>	Specific humidity of air within vegetation canopy space [$kgkg^{-1}$] Suffix ROT refers to variables on original two-dimensional arrays.
<i>wsnorot</i>	Liquid water content of snow pack [kgm^{-2}] Suffix ROT refers to variables on original two-dimensional arrays.
<i>cmairrot</i>	Aggregated mass of vegetation canopy [kgm^{-2}] Suffix ROT refers to variables on original two-dimensional arrays.
<i>refrot</i>	Suffix ROT refers to variables on original two-dimensional arrays.
<i>bcsnrot</i>	Suffix ROT refers to variables on original two-dimensional arrays.
<i>emisrot</i>	Suffix ROT refers to variables on original two-dimensional arrays.
<i>salbgat</i>	Suffix GAT refers to variables on gathered long vectors.
<i>csalgat</i>	Suffix GAT refers to variables on gathered long vectors.
<i>tbargat</i>	Temperature of soil layers [K] Suffix GAT refers to variables on gathered long vectors.
<i>thlqgat</i>	Volumetric liquid water content of soil layers [m^3m^{-3}] Suffix GAT refers to variables on gathered long vectors.
<i>thicgat</i>	Volumetric frozen water content of soil layers [m^3m^{-3}] Suffix GAT refers to variables on gathered long vectors.
<i>tsfsgat</i>	Ground surface temperature over subarea [K] Suffix GAT refers to variables on gathered long vectors.
<i>tpndgat</i>	Temperature of ponded water [K] Suffix GAT refers to variables on gathered long vectors.
<i>zpndgat</i>	Depth of ponded water on surface [m] Suffix GAT refers to variables on gathered long vectors.
<i>tbasgat</i>	Temperature of bedrock in third soil layer [K] Suffix GAT refers to variables on gathered long vectors.
<i>albsgat</i>	Snow albedo [] Suffix GAT refers to variables on gathered long vectors.
<i>tsnogat</i>	Snowpack temperature [K] Suffix GAT refers to variables on gathered long vectors.
<i>rhosgat</i>	Density of snow [kgm^{-3}] Suffix GAT refers to variables on gathered long vectors.
<i>snogat</i>	Mass of snow pack [kgm^{-2}] Suffix GAT refers to variables on gathered long vectors.
<i>gtgat</i>	Suffix GAT refers to variables on gathered long vectors.
<i>tcangat</i>	Vegetation canopy temperature [K] Suffix GAT refers to variables on gathered long vectors.
<i>rcangat</i>	Intercepted liquid water stored on canopy [kgm^{-2}] Suffix GAT refers to variables on gathered long vectors.
<i>scangat</i>	Intercepted frozen water stored on canopy [kgm^{-2}] Suffix GAT refers to variables on gathered long vectors.

<i>grogat</i>	Vegetation growth index [] Suffix GAT refers to variables on gathered long vectors.
<i>tacgat</i>	Temperature of air within vegetation canopy [K] Suffix GAT refers to variables on gathered long vectors.
<i>qacgat</i>	Specific humidity of air within vegetation canopy space [$kgkg^{-1}$] Suffix GAT refers to variables on gathered long vectors.
<i>wsnogat</i>	Liquid water content of snow pack [kgm^{-2}] Suffix GAT refers to variables on gathered long vectors.
<i>cmaigat</i>	Aggregated mass of vegetation canopy [kgm^{-2}] Suffix GAT refers to variables on gathered long vectors.
<i>refgat</i>	Suffix GAT refers to variables on gathered long vectors.
<i>bcsngat</i>	Suffix GAT refers to variables on gathered long vectors.
<i>emisgat</i>	Suffix GAT refers to variables on gathered long vectors.

The prognostic variables are scattered from the long, gathered arrays (collapsing the latitude and mosaic dimensions into one) back onto the original arrays using the pointer vectors generated in GATPREP.

6.19 src/CLASST.f File Reference

Purpose: Call subroutines to perform surface energy budget calculations.

Parameters

<i>nlandcs</i>	Number of modelled areas that contain subareas of canopy over bare ground / bare ground / canopy over snow / snow
<i>nlandgs</i>	Number of modelled areas that contain subareas of canopy over bare ground / bare ground / canopy over snow / snow
<i>nlandc</i>	Number of modelled areas that contain subareas of canopy over bare ground / bare ground / canopy over snow / snow
<i>nlandg</i>	Number of modelled areas that contain subareas of canopy over bare ground / bare ground / canopy over snow / snow
<i>nlandi</i>	Number of modelled areas that are ice sheets []
<i>isnoalb</i>	Switch to model snow albedo in two or more wavelength bands
<i>itc</i>	Flag to select iteration scheme for canopy temperature
<i>itcg</i>	Flag to select iteration scheme for surface under canopy
<i>itg</i>	Flag to select iteration scheme for ground or snow surface
<i>izref</i>	Flag governing treatment of surface roughness length
<i>islfd</i>	Flag governing options for surface stability functions and diagnostic calculations
<i>acond</i>	Diagnosed product of drag coefficient and wind speed over modelled area [ms^{-1}]
<i>cdh</i>	Surface drag coefficient for heat [(C_{DH})]
<i>cdm</i>	Surface drag coefficient for momentum [(C_{DM})]
<i>chcap</i>	Surface drag coefficient for momentum [(C_{DM})]
<i>chcaps</i>	Heat capacity of canopy over bare ground [$Jm^{-2}K^{-1}$]
<i>drag</i>	Surface drag coefficient under neutral stability []
<i>evap</i>	Diagnosed total surface water vapour flux over modelled area [$kgm^{-2}s^{-1}$]
<i>evapb</i>	Evaporation efficiency at ground surface []
<i>evapc</i>	Evaporation from vegetation over ground [ms^{-1}]
<i>evapcg</i>	Evaporation from ground under vegetation [ms^{-1}]
<i>evapcs</i>	Evaporation from vegetation over snow [ms^{-1}]
<i>evapg</i>	Evaporation from bare ground [ms^{-1}]
<i>evapgs</i>	Evaporation from snow on bare ground [ms^{-1}]
<i>evpcsg</i>	Evaporation from snow under vegetation [ms^{-1}]
<i>evppot</i>	Diagnosed potential evapotranspiration [$kgm^{-2}s^{-1}$](E_p)
<i>flgg</i>	Diagnosed net longwave radiation at soil surface [Wm^{-2}]
<i>flgs</i>	Diagnosed net longwave radiation at snow surface [Wm^{-2}]
<i>flgv</i>	Diagnosed net longwave radiation on vegetation canopy [Wm^{-2}]
<i>fsgg</i>	Diagnosed net shortwave radiation at soil surface [Wm^{-2}]
<i>fsgs</i>	Diagnosed net shortwave radiation at snow surface [Wm^{-2}]
<i>fsgv</i>	Diagnosed net shortwave radiation on vegetation canopy [Wm^{-2}]
<i>g12c</i>	Subarea heat flux between first and second soil layers [Wm^{-2}]
<i>g12cs</i>	Subarea heat flux between first and second soil layers [Wm^{-2}]
<i>g12g</i>	Subarea heat flux between first and second soil layers [Wm^{-2}]
<i>g12gs</i>	Subarea heat flux between first and second soil layers [Wm^{-2}]
<i>g23c</i>	Subarea heat flux between second and third soil layers [Wm^{-2}]
<i>g23cs</i>	Subarea heat flux between second and third soil layers [Wm^{-2}]
<i>g23g</i>	Subarea heat flux between second and third soil layers [Wm^{-2}]
<i>g23gs</i>	Subarea heat flux between second and third soil layers [Wm^{-2}]
<i>gt</i>	Diagnosed effective surface black-body temperature [K]($T_{0,eff}$)

<i>gtbs</i>	Surface temperature for CCCma black carbon scheme [K]
<i>gsnow</i>	Heat conduction into surface of snow pack [Wm^{-2}]
<i>gzeroc</i>	Subarea heat flux at soil surface [Wm^{-2}]
<i>gzerog</i>	Subarea heat flux at soil surface [Wm^{-2}]
<i>gzrocs</i>	Subarea heat flux at soil surface [Wm^{-2}]
<i>gzrogs</i>	Subarea heat flux at soil surface [Wm^{-2}]
<i>hbl</i>	Height of the atmospheric boundary layer [m]
<i>hcpc</i>	Heat capacity of soil layers under vegetation [$Jm^{-3}K^{-1}$]
<i>hcpg</i>	Heat capacity of soil layers in bare areas [$Jm^{-3}K^{-1}$]
<i>hevc</i>	Diagnosed latent heat flux on vegetation canopy [Wm^{-2}]
<i>hevg</i>	Diagnosed latent heat flux at soil surface [Wm^{-2}]
<i>hevs</i>	Diagnosed latent heat flux at snow surface [Wm^{-2}]
<i>hfsc</i>	Diagnosed sensible heat flux on vegetation canopy [Wm^{-2}]
<i>hfsg</i>	Diagnosed sensible heat flux at soil surface [Wm^{-2}]
<i>hfss</i>	Diagnosed sensible heat flux at snow surface [Wm^{-2}]
<i>hmfc</i>	Diagnosed energy associated with phase change of water on vegetation [Wm^{-2}]
<i>hmfn</i>	Diagnosed energy associated with phase change of water in snow pack [Wm^{-2}]
<i>htc</i>	Diagnosed internal energy change of soil layer due to conduction and/or change in mass [Wm^{-2}]
<i>htcc</i>	Diagnosed internal energy change of vegetation canopy due to conduction and/or change in mass [Wm^{-2}]
<i>htcs</i>	Diagnosed internal energy change of snow pack due to conduction and/or change in mass [Wm^{-2}]
<i>ilmo</i>	Inverse of Monin-Obukhov roughness length (m^{-1})
<i>iterct</i>	Counter of number of iterations required to solve surface energy balance for the elements of the four subareas
<i>qac</i>	Specific humidity of air within vegetation canopy space [$kgkg^{-1}$]
<i>qevap</i>	Diagnosed total surface latent heat flux over modelled area [Wm^{-2}]
<i>qfcf</i>	Sublimation from frozen water on vegetation [$kgm^{-2}s^{-1}$]
<i>qfcl</i>	Evaporation from liquid water on vegetation [$kgm^{-2}s^{-1}$]
<i>qfrezc</i>	Heat sink to be used for freezing water on ground under canopy [Wm^{-2}]
<i>qfrezg</i>	Heat sink to be used for freezing water on bare ground [Wm^{-2}]
<i>qg</i>	Diagnosed surface specific humidity [$kgkg^{-1}$]
<i>qlwavg</i>	Upwelling longwave radiation from land surface [Wm^{-2}]
<i>qmeltc</i>	Heat to be used for melting snow under canopy [Wm^{-2}]
<i>qmeltg</i>	Heat to be used for melting snow on bare ground [Wm^{-2}]
<i>qsens</i>	Diagnosed total surface sensible heat flux over modelled area [Wm^{-2}]
<i>raican</i>	Intercepted liquid water stored on canopy over ground [kgm^{-2}]
<i>raicns</i>	Intercepted liquid water stored on canopy over snow [kgm^{-2}]
<i>rhoscs</i>	Density of snow under vegetation [kgm^{-3}]
<i>rhosgs</i>	Density of snow in bare areas [kgm^{-3}]
<i>sfcubs</i>	Zonal surface wind velocity for CCCma black carbon scheme [ms^{-1}]
<i>sfcvbs</i>	Meridional surface wind velocity for CCCma black carbon scheme [ms^{-1}]
<i>snocan</i>	Intercepted frozen water stored on canopy over ground [kgm^{-2}]
<i>snocns</i>	Intercepted frozen water stored on canopy over snow [kgm^{-2}]
<i>sq</i>	Diagnosed screen-level specific humidity [$kgkg^{-1}$]
<i>srh</i>	Diagnosed screen-level relative humidity [%]
<i>st</i>	Diagnosed screen-level air temperature [K]

<i>su</i>	Diagnosed anemometer-level zonal wind [ms^{-1}]
<i>sv</i>	Diagnosed anemometer-level meridional wind [ms^{-1}]
<i>tac</i>	Temperature of air within vegetation canopy [K]
<i>tbarc</i>	Subarea temperatures of soil layers [C]
<i>tbarcs</i>	Subarea temperatures of soil layers [C]
<i>tbarg</i>	Subarea temperatures of soil layers [C]
<i>tbargs</i>	Subarea temperatures of soil layers [C]
<i>tcano</i>	Temperature of canopy over ground [K]
<i>tcans</i>	Temperature of canopy over snow [K]
<i>tcbotc</i>	Thermal conductivity of soil at bottom of layer [$Wm^{-1}K^{-1}$]
<i>tcbotg</i>	Thermal conductivity of soil at bottom of layer [$Wm^{-1}K^{-1}$]
<i>tctopc</i>	Thermal conductivity of soil at top of layer [$Wm^{-1}K^{-1}$]
<i>tctopg</i>	Thermal conductivity of soil at top of layer [$Wm^{-1}K^{-1}$]
<i>tcsnow</i>	Thermal conductivity of snow [$Wm^{-1}K^{-1}$]
<i>tflux</i>	Product of surface drag coefficient, wind speed and surface-air temperature difference [Kms^{-1}]
<i>thicec</i>	Frozen water content of soil layers under vegetation [m^3m^{-3}]
<i>thiceg</i>	Frozen water content of soil layers in bare areas [m^3m^{-3}]
<i>thliqc</i>	Liquid water content of soil layers under vegetation [m^3m^{-3}]
<i>thliqg</i>	Liquid water content of soil layers in bare areas [m^3m^{-3}]
<i>tpondc</i>	Subarea temperature of surface ponded water [C]
<i>tpondg</i>	Subarea temperature of surface ponded water [C]
<i>tpndcs</i>	Subarea temperature of surface ponded water [C]
<i>tpndgs</i>	Subarea temperature of surface ponded water [C]
<i>tsfsav</i>	Ground surface temperature over subarea [K]
<i>tsnocs</i>	Temperature of snow pack under vegetation [K]
<i>tsnogs</i>	Temperature of snow pack in bare areas [K]
<i>ue</i>	Friction velocity of air [ms^{-1}]
<i>ustarbs</i>	Friction velocity for CCCma black carbon scheme [ms^{-1}]
<i>wsnocs</i>	Liquid water content of snow pack under vegetation [kgm^{-2}]
<i>wsnogs</i>	Liquid water content of snow pack in bare areas [kgm^{-2}]
<i>wtable</i>	Depth of water table in soil [m]
<i>wtrg</i>	Diagnosed residual water transferred into or out of the soil [$kgm^{-2}s^{-1}$]
<i>zrefm</i>	Reference height associated with forcing wind speed [m]
<i>zrefh</i>	Reference height associated with forcing air temperature and humidity [m]
<i>zdiagm</i>	User-specified height associated with diagnosed anemometer-level wind speed [m]
<i>zdiagh</i>	User-specified height associated with diagnosed screen-level variables [m]
<i>vpd</i>	Vapour pressure deficit [mb]
<i>tadp</i>	Dew point temperature of air [K]
<i>rhoair</i>	Density of air [kgm^{-3}](ρ_a)
<i>qswinv</i>	Visible radiation incident on horizontal surface [Wm^{-2}]
<i>qswini</i>	Near-infrared radiation incident on horizontal surface [Wm^{-2}]
<i>qlwin</i>	Downwelling longwave radiation at bottom of atmosphere [Wm^{-2}]
<i>uwind</i>	Zonal component of wind speed [ms^{-1}](U_a)
<i>vwind</i>	Meridional component of wind speed [ms^{-1}](V_a)
<i>ta</i>	Air temperature at reference height [K](T_a)
<i>qa</i>	Specific humidity at reference height [gkg^{-1}]

First, two parameters are calculated for later use in the CLASST subroutines: the corrected wind speed v_a , and the Coriolis parameter f_{cor} (describing the effect of the earth's rotation on the movement of air according to the reference frame of the earth's surface). The wind speed correction is applied because it is assumed that air is never completely still, so v_a is specified as the maximum of VMOD and a limiting lower value of $0.1 m s^{-1}$. The Coriolis parameter is calculated from the angular velocity Ω of the earth's rotation (7.29×10^{-5} radians/s), and the latitude φ : $f_{cor} = 2\Omega \sin \varphi$

The packing and unpacking of binary files may cause small shifts in the values of variables at certain points in the model run, so checks are performed on the depth of ponded water and on the soil liquid and frozen moisture contents to ensure that unphysical values have not occurred. If the ponded water depth is vanishingly small or less than zero, it is set to zero. If the soil liquid water content falls below the set minimum value, it is set to the minimum value. If the soil frozen water content is less than zero, it is set back to zero. If the sum of the liquid water content and frozen water content converted to an equivalent liquid amount is greater than the pore volume, both are re-normalized by the pore volume. (This treatment of frozen water is employed in recognition of the fact that water expands upon freezing and can therefore occupy a greater volume than the nominal pore volume of the soil.) The small changes in internal energy and water content of the soil layers resulting from these operations are accounted for by updating the diagnostic variables HTC and WTRG.

If CLASS is being run in coupled mode with CTEM, several CTEM variables are initialized to zero. Subroutine TPREP is then called, to carry out the initialization of a number of variables and to do preparatory calculations of various parameters associated with the energy and water budget calculations.

The energy budget calculations that follow are performed over the four subareas, of canopy over snow (CS), snow over ground (GS), canopy over bare ground (C) and bare ground (G). First, a counter NLANDx is defined for each subarea, containing the number of modelled areas in which the subarea occurs. The subarea calculations are only done if the relevant counter is greater than zero. A counter NLANDI is also set to the number of modelled areas that are ice sheets (indicated by ISAND = -4). (This is used later in subroutine CLASSW to toggle the call to subroutine ICEBAL.)

For each subarea, the roughness lengths for momentum and heat, ZOM and ZOH, are obtained from their logarithms, and are then used to determine various height intervals in the atmosphere for subsequent calculations. These heights are derived from the input variables ZREFM and ZREFH, the reference heights corresponding to the input values of wind speed and of air temperature and humidity respectively, and ZDIAGM and ZDIAGH, the heights at which the diagnostic values of anemometer wind speed and screen level temperature and humidity are to be determined. The form of the calculations depends on the value of the flag IZREF. If IZREF = 1, the zero plane is taken to lie at the physical ground surface (as with field measurements); if IZREF = 2, the zero plane is taken to lie at the local roughness height for momentum (as with atmospheric models). The variables ZRSLDM and ZRSLDH are the height differences used in subroutine DRCOEF to express the interval between the conceptual bottom of the atmosphere and the reference heights for wind speed and for temperature and humidity respectively; the variables ZRSLFM and ZRSLFH are the corresponding height differences used in subroutine FLXSURFZ. If IZREF = 1, ZRSLDM and ZRSLDH are set to ZREFM and ZREFH minus the displacement height DISP or DISPS, and ZRSLFM and ZRSLFH are set to ZREFM and ZREFH minus the roughness length ZOM and DISP or DISPS. If IZREF = 2, ZRSLDM and ZRSLDH are set to ZREFM and ZREFH plus the roughness height ZOM, and ZRSLFM and ZRSLFH are set to ZREFM and ZREFH minus DISP or DISPS. (In the absence of a vegetation canopy, the displacement height is zero.) The variables ZDSLM and ZDSLH are the heights above the bottom of the modelled atmosphere at which the diagnostic values are to be calculated. If IZREF = 1, they are set to ZDIAGM and ZDIAGH minus ZOM; if IZREF = 2 they are simply set to ZDIAGM and ZDIAGH. At the end of the branch in the code, the ratios ZOSCLM and ZOSCLH, which are used in subroutine DRCOEF, are calculated as ZOM/ZRSLDM and ZOH/ZRSLDH respectively.

Several other local parameters are also calculated. The potential temperature is the temperature that air would have

if brought adiabatically (without addition or removal of heat) to a given height. The potential temperature of the air at the reference height, $T_{a,pot}$, is calculated relative to the height at which the horizontal wind speed goes to zero, using the dry adiabatic lapse rate, $dT/dz = -g/c_p$, where g is the acceleration due to gravity and c_p is the specific heat at constant pressure. Thus, $T_{a,pot} = T_a + z_{ref,h}g/c_p$ where T_a is the temperature of the air at the reference height and $z_{ref,h}$ is the height interval, equivalent to ZRSLFH defined above. If CLASS is being run coupled to an atmospheric model, i.e. if IZREF=2, the air temperature at the reference height has already been adiabatically extrapolated before being passed to CLASS. Otherwise, the correction is performed using the above equation.

The virtual potential temperature of the air at the reference height, $T_{a,v}$, is the potential temperature adjusted for the reduction in air density due to the presence of water vapour. This is applied in order to enable the use of the equation of state for dry air. $T_{a,v}$ can be approximated as: $T_{a,v} = T_{a,pot}[1 + 0.61q_a]$ where q_a is the specific humidity of the air at the reference height.

The bulk Richardson number Ri_B , used in the calculations of the atmospheric stability functions in subroutine DRCOEF, is formulated as: $Ri_B = [T_0 \sim T_{a,v}](-gz_{ref})/(T_{a,v}v_a^2)$ where T_0 is the surface temperature. For ease of calculation later on, the factor multiplying $[T_0 \sim T_{a,v}]$ on the right-hand side of the above equation is evaluated and assigned to a coefficient CRIB, using ZRSLDM for z_{ref} . The drag coefficient under neutral stability, C_{DN} , is expressed using basic flux-gradient analysis as: $C_{DN} = k^2/[ln(z_{ref}) \sim ln(z_0)]^2$ where k is the von Karman constant and z_0 is the roughness length. ZRSLDM is used for z_{ref} and the logarithm of the local roughness length for $ln(z_0)$, and the neutral drag coefficient DRAG over the modelled area is obtained as a weighted average over the four subareas.

For the two subareas with canopy cover, the wind speed of the air at the canopy top, $v_{a,c}$, is obtained by applying the classic logarithmic wind law for the wind speed $v(z)$ at a height z : $kv(z)/v_* = ln[(z \sim d)/z_0]$ where v_* is the friction velocity and d is the displacement height. Thus, $v_{a,c}$ at the canopy height H can be related to v_a at the reference height z_{ref} as: $v_{a,c} = v_a[ln(H \sim d) \sim ln(z_0)]/[ln(z_{ref}) \sim ln(z_0)]$

The vegetation height is calculated as $10z_0$. Local values of the temperature of the canopy air TAC and the humidity of the canopy air QAC are assigned to variables TACCS/TACCO and QACCS/QACCO respectively.

At this point calls are made to a series of subroutines addressing the calculation of the energy balance components of the subarea in question. The calls are summarized in the table below.

		CS	GS	C	G
CWCALC	Freezing/thawing of liquid/frozen water on canopy	YES		YES	
TNPREP	Set coefficients for temperature calculations in soil	YES	YES	YES	YES
TSPREP	Set coefficients for temperature calculations of snow	YES	YES		
TSOLVC	Calculate components of canopy energy balance	YES		YES	
TSOLVE	Calculate components of ground or snow energy balance		YES		YES
TSPOST	Heat conduction in snow pack	YES	YES		
TNPOST	Heat conduction in soil	YES	YES	YES	YES

After these calls, various diagnostic calculations are performed. First the screen-level temperature and humidity, and the anemometer-level zonal and meridional wind speeds, are calculated. Three options are provided for doing this, indicated by the flag ISLFD. If ISLFD = 0, a simple similarity-based approach is used. (This is currently the standard option in the AGCM.) The ratio (RATIOM) of the square root of the surface drag coefficient for momentum C_{DM} to that of the neutral drag coefficient C_{DN} for the anemometer height is calculated, and an analogous calculation is performed for the ratio (RATIOH) of the square root of the surface drag coefficient for heat C_{DH} to that of the neutral drag coefficient for the screen height z_s , to give a measure of the degree of atmospheric instability. If the bulk Richardson number RIB is negative (indicating unstable conditions), the ratio used for the temperature and humidity is the minimum of RATIOH and $(z_s / z_{ref})^{1/3}$, a measure of the depth of convection. These ratios are applied to the calculation of the screen and anemometer level variables. If the ratios are large, indicating strong coupling with the atmosphere, the screen level variables tend toward the values at the reference height; if the ratio is small, they tend to the values at the surface. At the end of the block of code, the CCCma subroutine SCREENRH is called to evaluate the screen-level relative humidity, and the grid-cell average values of the screen and anemometer level diagnostic variables are incremented. For the bare soil subarea, the zonal and meridional anemometer-level wind speeds, the friction velocity and the surface temperature are saved separately as inputs to the CCCma black carbon deposition scheme (Namazi et al., 2015) [Namazi2015-wz].

If ISLFD= 1 or 2, the more complex calculations in subroutines SLDIAG and DIASURFZ are followed for the screen-level and anemometer-level diagnostics. The calculations done in SLDIAG are consistent with the modelling ap-

proach used in subroutine DRCOEF to determine the atmospheric stability functions, so when ISLFD = 1, DRCOEF and SLDIAG are called. The calculations done in DIASURFZ are consistent with the modelling approach used in subroutine FLXSURFZ for the atmospheric stability functions, so when ISLFD = 2, FLXSURFZ and DIASURFZ are called.

A number of additional diagnostic variables are calculated as weighted averages over the four subareas. For the most part, these calculations are straightforward; only the calculation of the potential evapotranspiration E_p (EVPPOT) involves some complexity. E_p is defined as the evapotranspiration that would occur under ambient atmospheric conditions if the soil were completely saturated and the vegetation canopy were completely water-covered, i.e. if there were no surface resistances to evaporation: $E_p = \rho_a C_{DH} v_a [q_{0,sat} - q_a]$ where ρ_a is the density of air and $q_{0,sat}$ is the saturated specific humidity at the surface. For the ground or snow surface $q_{0,sat}$ was calculated in subroutine TSOLVE. For the canopy, the saturated specific humidity at the canopy air temperature, $q_{ac,sat}$, is used. This is obtained from the mixing ratio at saturation, $w_{ac,sat}$: $q_{ac,sat} = w_{ac,sat} / [1 + w_{ac,sat}]$

The mixing ratio is a function of the saturation vapour pressure $e_{ac,sat}$ at the canopy air temperature: $w_{ac,sat} = 0.622 e_{ac,sat} / (p_{dry})$

A standard empirical equation for the saturation vapour pressure dependence on the temperature T is used:

$$e_{sat} = 611.0 \exp[17.269(T - T_f) / (T - 35.86)] T \geq T_f$$

$$e_{sat} = 611.0 \exp[21.874(T - T_f) / (T - 7.66)] T < T_f$$

where T_f is the freezing point.

At the end of the blocks of code dealing with the four subareas, several more diagnostic variables are evaluated. Again, these calculations are generally straightforward. The effective black-body surface temperature $T_{0,eff}$ is obtained by inverting the Stefan-Boltzmann equation: $L \uparrow = \sigma T_{0,eff}^4$ where $L \uparrow$ is the outgoing longwave radiation and σ is the Stefan-Boltzmann constant. The evaporation efficiency parameter EVAPB is calculated as the ratio of the actual evapotranspiration to the potential evapotranspiration.

Purpose: Call subroutines to perform surface water budget calculations.

6.20.2 Function/Subroutine Documentation

6.20.2.1 subroutine classw (real, dimension (ilg,ig) *THLIQ*, real, dimension (ilg,ig) *THICE*, real, dimension (ilg,ig) *TBAR*, real, dimension (ilg) *TCAN*, real, dimension (ilg) *RCAN*, real, dimension (ilg) *SNCAN*, real, dimension (ilg) *RUNOFF*, real, dimension (ilg) *TRUNOF*, real, dimension (ilg) *SNO*, real, dimension (ilg) *TSNOW*, real, dimension (ilg) *RHOSNO*, real, dimension (ilg) *ALBSNO*, real, dimension (ilg) *WSNOW*, real, dimension (ilg) *ZPOND*, real, dimension (ilg) *TPOND*, real, dimension (ilg) *GROWTH*, real, dimension (ilg) *TBASE*, real, dimension (ilg,ig) *GFLUX*, real, dimension (ilg) *PCFC*, real, dimension (ilg) *PCLC*, real, dimension (ilg) *PCPN*, real, dimension (ilg) *PCPG*, real, dimension (ilg) *QFCF*, real, dimension (ilg) *QFCL*, real, dimension (ilg) *QFN*, real, dimension (ilg) *QFG*, real, dimension (ilg,ig) *QFC*, real, dimension (ilg) *HMFC*, real, dimension (ilg,ig) *HMFG*, real, dimension (ilg) *HMFN*, real, dimension (ilg) *HTCC*, real, dimension (ilg) *HTCS*, real, dimension (ilg,ig) *HTC*, real, dimension (ilg) *ROFC*, real, dimension (ilg) *ROFN*, real, dimension (ilg) *ROVG*, real, dimension (ilg) *WTRS*, real, dimension (ilg) *WTRG*, real, dimension (ilg) *OVRFLW*, real, dimension (ilg) *SUBFLW*, real, dimension (ilg) *BASFLW*, real, dimension (ilg) *TOVRFL*, real, dimension (ilg) *TSUBFL*, real, dimension (ilg) *TBASFL*, real, dimension (ilg) *EVAP*, real, dimension (ilg) *QFLUX*, real, dimension (ilg) *RHOAIR*, real, dimension (ilg,ig) *TBARC*, real, dimension (ilg,ig) *TBARG*, real, dimension (ilg,ig) *TBARCS*, real, dimension (ilg,ig) *TBARGS*, real, dimension (ilg,ig) *THLIQC*, real, dimension (ilg,ig) *THLIQG*, real, dimension (ilg,ig) *THICEC*, real, dimension (ilg,ig) *THICEG*, real, dimension (ilg,ig) *HCPC*, real, dimension (ilg,ig) *HCPG*, real, dimension (ilg) *RPCP*, real, dimension (ilg) *TRPCP*, real, dimension (ilg) *SPCP*, real, dimension (ilg) *TSPCP*, real, dimension (ilg) *PCPR*, real, dimension (ilg) *TA*, real, dimension (ilg) *RHOSNI*, real, dimension (ilg) *GGEO*, real, dimension (ilg) *FC*, real, dimension (ilg) *FG*, real, dimension (ilg) *FCS*, real, dimension (ilg) *FGS*, real, dimension (ilg) *TPONDG*, real, dimension (ilg) *TPNDGS*, real, dimension (ilg) *EVAPC*, real, dimension (ilg) *EVAPCG*, real, dimension (ilg) *EVAPG*, real, dimension (ilg) *EVAPCS*, real, dimension (ilg) *EVPCSG*, real, dimension (ilg) *EVAPGS*, real, dimension (ilg) *QFREZC*, real, dimension (ilg) *QFREZG*, real, dimension (ilg) *QMELTC*, real, dimension (ilg) *QMELTG*, real, dimension (ilg) *RAICAN*, real, dimension (ilg) *SNOCAN*, real, dimension (ilg) *RAICNS*, real, dimension (ilg) *SNOCNS*, real, dimension (ilg) *FSVF*, real, dimension (ilg) *FSVFS*, real, dimension (ilg) *CWLCAP*, real, dimension (ilg) *CWFCAP*, real, dimension (ilg) *CWLCPS*, real, dimension (ilg) *CWFCPS*, real, dimension (ilg) *TCANO*, real, dimension (ilg) *TCANS*, real, dimension (ilg) *CHCAP*, real, dimension (ilg) *CHCAPS*, real, dimension (ilg) *CMASSC*, real, dimension (ilg) *CMASSCS*, real, dimension (ilg) *ZSNOW*, real, dimension (ilg) *GZEROC*, real, dimension (ilg) *GZEROG*, real, dimension (ilg) *GZROCS*, real, dimension (ilg) *GZROGS*, real, dimension (ilg) *G12C*, real, dimension (ilg) *G12G*, real, dimension (ilg) *G12CS*, real, dimension (ilg) *G12GS*, real, dimension (ilg) *G23C*, real, dimension (ilg) *G23G*, real, dimension (ilg) *G23CS*, real, dimension (ilg) *G23GS*, real, dimension (ilg) *TSNOCS*, real, dimension (ilg) *TSNOGS*, real, dimension (ilg) *WSNOCS*, real, dimension (ilg) *WSNOGS*, real, dimension (ilg) *RHOSCS*, real, dimension (ilg) *RHOSGS*, real, dimension (ilg) *ZPLIMC*, real, dimension (ilg) *ZPLIMG*, real, dimension (ilg) *ZPLMCS*, real, dimension (ilg) *ZPLMGS*, real, dimension (ilg,4) *TSFSAV*, real, dimension (ilg,ig) *TCTOPC*, real, dimension (ilg,ig) *TCBOTC*, real, dimension (ilg,ig) *TCTOPG*, real, dimension (ilg,ig) *TCBOTG*, real, dimension (ilg,ig) *FROOT*, real, dimension (ilg,ig) *FROOTS*, real, dimension (ilg,ig) *THPOR*, real, dimension (ilg,ig) *THLRET*, real, dimension (ilg,ig) *THLMIN*, real, dimension (ilg,ig) *BI*, real, dimension (ilg,ig) *PSISAT*, real, dimension (ilg,ig) *GRKSAT*, real, dimension (ilg,ig) *THLRAT*, real, dimension (ilg,ig) *THFC*, real, dimension (ilg) *XDRAIN*, real, dimension (ilg,ig) *HCPS*, real, dimension (ilg) *DELZ*, real, dimension (ilg,ig) *DELZW*, real, dimension (ilg,ig) *ZBOTW*, real, dimension (ilg) *XSLOPE*, real, dimension (ilg) *GRKFAC*, real, dimension (ilg) *WFSURF*, real, dimension (ilg) *WFCINT*, integer, dimension (ilg,ig) *ISAND*, integer, dimension (ilg) *IGDR*, integer *IWF*, integer *ILG*, integer *IL1*, integer *IL2*, integer *N*, integer *JL*, integer *IC*, integer *IG*, integer *IGP1*, integer *IGP2*, integer *NLANDCS*, integer *NLANDGS*, integer *NLANDC*, integer *NLANDG*, integer *NLANDI*)

Parameters

<i>iwf</i>	Flag governing lateral soil water flow calculations
<i>nlandcs</i>	Number of modelled areas that contain subareas of canopy over snow
<i>nlandgs</i>	Number of modelled areas that contain subareas of snow
<i>nlandc</i>	Number of modelled areas that contain subareas of canopy over bare ground
<i>nlandg</i>	Number of modelled areas that contain subareas of bare ground
<i>nlandi</i>	Number of modelled areas that are ice sheets []
<i>thliq</i>	Volumetric liquid water content of soil layers [$m^3 m^{-3}$]
<i>thice</i>	Volumetric frozen water content of soil layers [$m^3 m^{-3}$]
<i>tbar</i>	Temperature of soil layers [K]
<i>gflux</i>	Heat flux at interfaces between soil layers [$W m^{-2}$]
<i>tcan</i>	Vegetation canopy temperature [K]
<i>rcan</i>	Intercepted liquid water stored on canopy [$kg m^{-2}$]
<i>sncan</i>	Intercepted frozen water stored on canopy [$kg m^{-2}$]
<i>runoff</i>	Total runoff from soil [$morkg m^{-2} s^{-1}$]
<i>sno</i>	Mass of snow pack [$kg m^{-2}$]
<i>tsnow</i>	Snowpack temperature [K]
<i>rhosno</i>	Density of snow [$kg m^{-3}$]
<i>albsno</i>	Snow albedo []
<i>zpond</i>	Depth of ponded water on surface [m]
<i>tpond</i>	Temperature of ponded water [K]
<i>growth</i>	Vegetation growth index []
<i>tbase</i>	Temperature of bedrock in third soil layer [K]
<i>trunof</i>	Temperature of total runoff [K]
<i>wsnow</i>	Liquid water content of snow pack [$kg m^{-2}$]
<i>pcfc</i>	Frozen precipitation intercepted by vegetation [$kg m^{-2} s^{-1}$]
<i>pcl</i>	Liquid precipitation intercepted by vegetation [$kg m^{-2} s^{-1}$]
<i>pcpn</i>	Precipitation incident on snow pack [$kg m^{-2} s^{-1}$]
<i>pcpg</i>	Precipitation incident on ground [$kg m^{-2} s^{-1}$]
<i>qfcf</i>	Sublimation from frozen water on vegetation [$kg m^{-2} s^{-1}$]
<i>qfcl</i>	Evaporation from liquid water on vegetation [$kg m^{-2} s^{-1}$]
<i>qfn</i>	Sublimation from snow pack [$kg m^{-2} s^{-1}$]
<i>qfg</i>	Evaporation from ground [$kg m^{-2} s^{-1}$]
<i>hmfc</i>	Diagnosed energy associated with phase change of water on vegetation [$W m^{-2}$]
<i>hmfn</i>	Diagnosed energy associated with phase change of water in snow pack [$W m^{-2}$]
<i>htcc</i>	Diagnosed internal energy change of vegetation canopy due to conduction and/or change in mass [$W m^{-2}$]
<i>htcs</i>	Diagnosed internal energy change of snow pack due to conduction and/or change in mass [$W m^{-2}$]
<i>rofc</i>	Liquid/frozen water runoff from vegetation [$kg m^{-2} s^{-1}$]
<i>rofn</i>	Liquid water runoff from snow pack [$kg m^{-2} s^{-1}$]
<i>rov</i>	Liquid/frozen water runoff from vegetation to ground surface [$kg m^{-2} s^{-1}$]
<i>wtrs</i>	Diagnosed residual water transferred into or out of the snow pack [$kg m^{-2} s^{-1}$]
<i>wtrg</i>	Diagnosed residual water transferred into or out of the soil [$kg m^{-2} s^{-1}$]
<i>ovrflw</i>	Overland flow from top of soil column

<i>subflw</i>	Interflow from sides of soil column [$kgm^{-2}s^{-1}$]
<i>basflw</i>	Base flow from bottom of soil column [$morkgm^{-2}s^{-1}$]
<i>tovrfl</i>	Temperature of overland flow from top of soil column [K]
<i>tsubfl</i>	Temperature of interflow from sides of soil column [K]
<i>tbasfl</i>	Temperature of base flow from bottom of soil column [K]
<i>evap</i>	Diagnosed total surface water vapour flux over modelled area [$kgm^{-2}s^{-1}$]
<i>qflux</i>	Product of surface drag coefficient, wind speed and surface-air specific humidity difference [ms^{-1}]
<i>rhoair</i>	Density of air [kgm^{-3}]
<i>qfc</i>	Water removed from soil layers by transpiration [$kgm^{-2}s^{-1}$]
<i>hmfq</i>	Diagnosed energy associated with phase change of water in soil layers [Wm^{-2}]
<i>htc</i>	Diagnosed internal energy change of soil layer due to conduction and/or change in mass [Wm^{-2}]
<i>rpcp</i>	Rainfall rate over modelled area [ms^{-1}]
<i>trpcp</i>	Rainfall temperature over modelled area [C]
<i>spcp</i>	Snowfall rate over modelled area [ms^{-1}]
<i>tspcp</i>	Snowfall temperature over modelled area [C]
<i>pcpr</i>	Surface precipitation rate [$kgm^{-2}s^{-1}$]
<i>ta</i>	Air temperature at reference height [K]
<i>tbarc</i>	Subarea temperatures of soil layers [C]
<i>tbarg</i>	Subarea temperatures of soil layers [C]
<i>tbarcs</i>	Subarea temperatures of soil layers [C]
<i>tbargs</i>	Subarea temperatures of soil layers [C]
<i>thliqc</i>	Liquid water content of soil layers under vegetation [m^3m^{-3}]
<i>thliqg</i>	Liquid water content of soil layers in bare areas [m^3m^{-3}]
<i>thicec</i>	Frozen water content of soil layers under vegetation [m^3m^{-3}]
<i>thiceg</i>	Frozen water content of soil layers in bare areas [m^3m^{-3}]
<i>hcpc</i>	Heat capacity of soil layers under vegetation [$Jm^{-3}K^{-1}$]
<i>hpcg</i>	Heat capacity of soil layers in bare areas [$Jm^{-3}K^{-1}$]
<i>tctopc</i>	Thermal conductivity of soil at top of layer (vegetation over ground) [$Wm^{-1}K^{-1}$]
<i>tcbotc</i>	Thermal conductivity of soil at bottom of layer (vegetation over ground) [$Wm^{-1}K^{-1}$]
<i>tctopg</i>	Thermal conductivity of soil at top of layer (bare ground) [$Wm^{-1}K^{-1}$]
<i>tcbotg</i>	Thermal conductivity of soil at bottom of layer (bare ground) [$Wm^{-1}K^{-1}$]
<i>froot</i>	Fraction of total transpiration contributed by soil layer over snow-free subarea []
<i>froots</i>	Fraction of total transpiration contributed by soil layer over snow-covered subarea []
<i>tsfsav</i>	Ground surface temperature over subarea [K]
<i>fc</i>	Subarea fractional coverage of modelled area []
<i>fg</i>	Subarea fractional coverage of modelled area []
<i>fcs</i>	Subarea fractional coverage of modelled area []
<i>fgs</i>	Subarea fractional coverage of modelled area []
<i>tpondc</i>	Subarea temperature of surface ponded water [C]
<i>tpondg</i>	Subarea temperature of surface ponded water [C]
<i>tpndcs</i>	Subarea temperature of surface ponded water [C]
<i>tpndgs</i>	Subarea temperature of surface ponded water [C]
<i>evapc</i>	Evaporation from vegetation over ground [ms^{-1}]
<i>evapcg</i>	Evaporation from ground under vegetation [ms^{-1}]
<i>evapg</i>	Evaporation from bare ground [ms^{-1}]
<i>evapcs</i>	Evaporation from vegetation over snow [ms^{-1}]

<i>evpcsg</i>	Evaporation from snow under vegetation [ms^{-1}]
<i>evapgs</i>	Evaporation from snow on bare ground [ms^{-1}]
<i>qfrezc</i>	Heat sink to be used for freezing water on ground under canopy [Wm^{-2}]
<i>qfrezg</i>	Heat sink to be used for freezing water on bare ground [Wm^{-2}]
<i>qmeltc</i>	Heat to be used for melting snow under canopy [Wm^{-2}]
<i>qmeltg</i>	Heat to be used for melting snow on bare ground [Wm^{-2}]
<i>raican</i>	Intercepted liquid water stored on canopy over ground [kgm^{-2}]
<i>snocan</i>	Intercepted frozen water stored on canopy over ground [kgm^{-2}]
<i>raicns</i>	Intercepted liquid water stored on canopy over snow [kgm^{-2}]
<i>snocns</i>	Intercepted frozen water stored on canopy over snow [kgm^{-2}]
<i>fsvf</i>	Sky view factor of ground under vegetation canopy []
<i>fsvfs</i>	Sky view factor of snow under vegetation canopy []
<i>cwlcap</i>	Storage capacity of canopy over bare ground for liquid water [kgm^{-2}]
<i>cwfcap</i>	Storage capacity of canopy over bare ground for frozen water [kgm^{-2}]
<i>cwlcps</i>	Storage capacity of canopy over snow for liquid water [kgm^{-2}]
<i>cwfcps</i>	Storage capacity of canopy over snow for frozen water [kgm^{-2}]
<i>tcano</i>	Temperature of canopy over ground [K]
<i>tcans</i>	Temperature of canopy over snow [K]
<i>chcap</i>	Heat capacity of canopy over bare ground [$Jm^{-2}K^{-1}$]
<i>chcaps</i>	Heat capacity of canopy over snow [$Jm^{-2}K^{-1}$]
<i>cmassc</i>	Mass of canopy over bare ground [kgm^{-2}]
<i>cmasc</i>	Mass of canopy over snow [kgm^{-2}]
<i>zsnow</i>	Depth of snow pack [m]
<i>rhosni</i>	Density of fresh snow [kgm^{-3}]
<i>gzeroc</i>	Subarea heat flux at soil surface [Wm^{-2}]
<i>gzerog</i>	Subarea heat flux at soil surface [Wm^{-2}]
<i>gzrocs</i>	Subarea heat flux at soil surface [Wm^{-2}]
<i>gzrogs</i>	Subarea heat flux at soil surface [Wm^{-2}]
<i>g12c</i>	Subarea heat flux between first and second soil layers [Wm^{-2}]
<i>g12g</i>	Subarea heat flux between first and second soil layers [Wm^{-2}]
<i>g12cs</i>	Subarea heat flux between first and second soil layers [Wm^{-2}]
<i>g12gs</i>	Subarea heat flux between first and second soil layers [Wm^{-2}]
<i>g23c</i>	Subarea heat flux between second and third soil layers [Wm^{-2}]
<i>g23g</i>	Subarea heat flux between second and third soil layers [Wm^{-2}]
<i>g23cs</i>	Subarea heat flux between second and third soil layers [Wm^{-2}]
<i>g23gs</i>	Subarea heat flux between second and third soil layers [Wm^{-2}]
<i>tsnocs</i>	Temperature of snow pack under vegetation [K]
<i>tsnogs</i>	Temperature of snow pack in bare areas [K]
<i>wsnocs</i>	Liquid water content of snow pack under vegetation [kgm^{-2}]
<i>wsnogs</i>	Liquid water content of snow pack in bare areas [kgm^{-2}]
<i>rhoscs</i>	Density of snow under vegetation [kgm^{-3}]
<i>rhosgs</i>	Density of snow in bare areas [kgm^{-3}]
<i>zplimc</i>	Subarea maximum ponding depth [m]
<i>zplimg</i>	Subarea maximum ponding depth [m]
<i>zplmcs</i>	Subarea maximum ponding depth [m]
<i>zplmgs</i>	Subarea maximum ponding depth [m]
<i>ggeo</i>	Geothermal heat flux at bottom of soil profile [Wm^{-2}]

<i>thpor</i>	Pore volume in soil layer [m^3m^{-3}]
<i>thlret</i>	Liquid water retention capacity for organic soil [$m^3 m^{-3}$]
<i>thlmin</i>	Residual soil liquid water content remaining after freezing or evaporation [m^3m^{-3}]
<i>bi</i>	Clapp and Hornberger empirical "b" parameter []
<i>grksat</i>	Saturated hydraulic conductivity of soil layer [ms^{-1}]
<i>psisat</i>	Soil moisture suction at saturation [m]
<i>thlrat</i>	Fractional saturation of soil behind the wetting front []
<i>thfc</i>	Field capacity [m^3m^{-3}]
<i>hcps</i>	Heat capacity of soil material [$Jm^{-3}K^{-1}$]
<i>delzw</i>	Overall thickness of soil layer [m]
<i>zbotw</i>	Depth to permeable bottom of soil layer [m]
<i>xdrain</i>	Drainage index at bottom of soil profile []
<i>xslope</i>	Surface slope (used when running MESH code) [degrees]
<i>grkfacs</i>	WATROF parameter used when running MESH code []
<i>wfsurf</i>	WATROF parameter used when running MESH code []
<i>wfcint</i>	WATROF parameter used when running MESH code []
<i>delz</i>	Overall thickness of soil layer [m]
<i>isand</i>	Sand content flag
<i>igdr</i>	Index of soil layer in which bedrock is encountered

First, subroutine WPREP is called to initialize various arrays and produce parameters for the four subareas of canopy over snow (CS), snow on ground (GS), canopy over ground (C) and bare ground (G). Then, for each of the four subareas, if the number of modelled areas containing that subarea is greater than zero, a series of subroutines is called. The subroutines associated with each subarea are listed in the table below.

CANVAP	Evaporation/sublimation of water from vegetation canopy	CS,C
CANADD	Addition of rainfall/snowfall to canopy; throughfall and drip	CS,C
CWCALC	Freezing/thawing of liquid/frozen water on canopy	CS,C
SUBCAN	Precipitation and condensation under canopy	CS,C
TWCALC	Freezing/thawing of liquid/frozen water in soil	CS,GS,C,G
SNOVAP	Sublimation from snow pack	CS,GS,C,G
TFREEZ	Freezing of ponded water on soil	CS,GS,C,G
TMELT	Melting of snow pack	CS,GS
SNOADD	Accumulation of snow on ground	CS,GS,C,G
SNINFL	Infiltration of rain into snow pack	CS,GS
ICEBAL	Energy and water budget of ice sheets	GS,G
GRINFL	Infiltration of water into soil	CS,GS,C,G
GRDRAN	Soil water movement in response to gravity and suction forces	CS,GS,C,G
TMCALC	Step ahead soil layer temperatures, check for freezing/thawing	CS,GS,C,G
CHKWAT	Check subarea moisture balances for closure	CS,GS,C,G
SNOALBW	Temporal variation of snow albedo and density	CS,GS

After these calls have been done, average values of the main prognostic variables over the modelled area are determined by performing weighted averages over the four subareas, and checks are carried out to identify and remove vanishingly small values. First the bedrock temperature in the third soil layer, the total runoff and the runoff temperature are calculated. Then the total runoff and the overland flow, interflow and baseflow are converted from units of m to $kgm^{-2}s^{-1}$. The total surface water vapour flux over the modelled area is updated to account for the residual amounts of evaporative demand over the four subareas that could not be supplied by surface stores (WLSTCS, WLSTGS, WLOSTC and WLOSTG, variables that are defined internally in this subroutine), and the diagnostic variable QFLUX is evaluated.

The temperature of the vegetation canopy TCAN and the amount of intercepted liquid water RCAN are calculated as weighted averages over the two canopy subareas. A flag is set to trigger a call to abort if TCAN is less than -100 C or greater than 100 C. If RCAN is vanishingly small, it is added to the overland flow and to the total runoff, and their respective temperatures are recalculated. The diagnostic arrays ROFC, ROVG, PCPG and HTCC are updated, and RCAN is set to zero. The amount of intercepted snow SNCAN is likewise calculated as a weighted average over the two canopy subareas. If SNCAN is vanishingly small, it is added to the overland flow and to the total runoff, and their respective temperatures are recalculated. The diagnostic arrays ROFC, ROVG, PCPG and HTCC are updated, and SNCAN is set to zero. If there is no canopy present, TCAN is set to zero.

At the end of the 600 loop, the depth of ponded water ZPOND and its temperature TPOND over the modelled area are calculated as weighted averages over the four subareas. If ZPOND is vanishingly small, then as in the case of intercepted water, it is added to the overland flow and to the total runoff, and their respective temperatures are recalculated. The diagnostic array HTC is updated, ZPOND is set to zero and TPOND is set to 0 °C.

In the 650 loop, values of the snow prognostic variables are calculated as weighted averages over the four subareas. The weightings for the subareas include the four internally-defined CLASSW variables XSNOCs, XSNOGs, XSNOWC and XSNOWG, which are set in subroutine CHKWAT to 1 if the subarea snow depth is greater than zero, and to zero otherwise. If the snow depth over the CS and GS subareas is greater than zero (meaning that there was a pre-existing snow cover at the beginning of the time step), the average snow albedo ALBSNO is preferentially set to the average over these two subareas. Otherwise ALBSNO is set to the average over the C and G subareas (where snow has just been added in the current time step). The snow temperature TSNOW and density RHOSNO are set to weighted averages over the four subareas, using the internally-defined subarea volumetric heat capacities HCPCS/GS/C/G and RHOSCS/GS/C/G. Finally the snow depth ZSNOW is calculated from the subarea depths; the liquid water content of the snow pack WSNOW is obtained as a weighted average over the CS and GS subareas (assuming that freshly fallen snow does not yet contain liquid water); and the snow mass is determined from ZSNOW and RHOSNO. Upper and lower limits apply to the snow pack. If the snow depth exceeds 10 m, the excess snow and its associated liquid water content are added to the overland flow and the total runoff, the respective temperatures of the latter are recalculated and the diagnostic arrays ROFN, PCPG and HTCS are updated. As in the case of intercepted and ponded water, if the snow mass is vanishingly small it and its liquid water content are added to the overland flow and to the total runoff, and their respective temperatures are recalculated, the diagnostic arrays ROFN, PCPG and HTCS are updated, and TSNOW, RHOSNO, SNO and WSNOW are set to zero. Flags are set to trigger calls to abort if TSNOW is less than 0 K or greater than 0.001 C. Finally, the three abort flags set thus far are checked, and calls to abort are performed if they are greater than zero.

In the 700 loop, the temperature of each soil layer is calculated as a weighted average over the four subareas. In the case of the third soil layer, if the standard three-layer configuration is being modelled (with a very thick third soil layer of 3.75 m), the subarea layer temperatures TBARCS/GS/C/G and the layer heat capacities HCPCS/GS/C/G apply to the permeable depth DELZW of the layer, and the bedrock temperature TBASE and the rock heat capacity HCPSND to the remainder, DELZ-DELZW. The averaging is carried out accordingly. In all other soil layers, the layer temperature applies to the whole thickness, whose heat capacity is a weighted average of HCPCS/GS/C/G over DELZW and HCPSND over DELZ-DELZW. The volumetric liquid water content THLIQ, the volumetric frozen water content THICE, and the heat flux at the soil layer interfaces GFLUX are calculated as simple weighted averages over the subareas. A flag is set to trigger a call to abort if the soil layer temperature is less than -100 C or greater than 100 C, and after the end of the loop, a call to abort is performed if the flag is greater than zero.

Finally, subroutine CGROW is called to update the vegetation growth index.

6.21 src/CLASSZ.f File Reference

Purpose: Check for energy and water balance closure over modelled area.

Functions/Subroutines

- subroutine [classz](#) (ISTEP, CTVSTP, CTSSTP, CT1STP, CT2STP, CT3STP, WTVSTP, WTSSTP, WTGSTP, FLOW, SGV, FLGV, HFSC, HEVC, HMFC, HTCC, FSGS, FLGS, HFSS, HEVS, HMFN, HTCS, FSGG, FLGG, HFSG, HEVG, HMFG, HTC, PCFC, PCLC, QFCF, QFCL, ROFC, WTRC, PCPN, QFN, ROFN, WTRS, PCPG, QFG, QFC, ROF, WTRG, CMAI, RCAN, SCAN, TCAN, SNO, WSNOW, TSNOW, THLIQ, THICE, HCPS, THPOR, DELZW, TBAR, ZPOND, TPOND, DELZ, FCS, FGS, FC, FG, IL1, IL2, ILG, IG, N)

6.21.1 Detailed Description

Purpose: Check for energy and water balance closure over modelled area.

In this subroutine, checks are carried out to ensure that the change in energy storage in each of the components of the modelled area (canopy, snow and soil) is equal to the sum of the energy fluxes into and out of them; and that the change in moisture storage in each of the components is equal to the sum of the water fluxes into and out of them. The subroutine is called twice, once at the beginning (ISTEP=0) and once at the end (ISTEP=1) of each time step. At the beginning, the instantaneous energy and moisture storage terms are evaluated, and at the end the differences over the time step are calculated:

$$\text{Change in canopy energy storage} = \Delta[(c_c W_c + c_w W_{l,c} + c_i W_{f,c})T_c]/\Delta t$$

$$\text{Change in snow energy storage} = \Delta[(C_i W_s/\rho_i + C_w W_{l,s}/\rho_w)T_s]/\Delta t$$

$$\text{Change in soil layer energy storage} = \Delta[(C_w \theta_l + C_i \theta_f + C_g \theta_g)\Delta z_w + C_b(\Delta z - \Delta z_w)]T_g/\Delta t \text{ (For the first soil layer, the numerator contains the additional term } C_w z_p T_p.)$$

$$\text{Change in canopy moisture storage} = \Delta[W_{l,c} + W_{f,c}]$$

$$\text{Change in snow moisture storage} = \Delta[W_s + W_{l,s}]$$

$$\text{Change in soil moisture storage} = \Delta[(\theta_l \rho_w + \theta_f \rho_i)\Delta z_w + z_p \rho_w]$$

The net energy and moisture fluxes are also evaluated at the end of the time step:

$$\text{Net energy flux for canopy} = K_{*,c} + L_{*,c} - Q_{H,c} - Q_{E,c} - Q_{M,c} + Q_{I,c}$$

$$\text{Net energy flux for snow} = K_{*,s} + L_{*,s} - Q_{H,s} - Q_{E,s} - Q_{M,s} + Q_{I,s}$$

$$\text{Net energy flux for first soil layer} = K_{*,g} + L_{*,g} - Q_{H,g} - Q_{E,g} - Q_{M,1} + Q_{I,1}$$

$$\text{Net energy flux for other soil layers} = -Q_{M,j} + Q_{I,j}$$

$$\text{Net moisture flux for canopy} = P_{l,c} + P_{f,c} - E_{l,c} - E_{f,c} - R_c + A_c$$

$$\text{Net moisture flux for snow} = P_s - E_s - R_s + A_s$$

$$\text{Net moisture flux for soil} = P_g - E_g - R_g + A_g - E_c$$

In these equations the K_* terms refer to net shortwave radiation, the L_* terms to net longwave radiation, the Q_H terms to sensible heat flux, the Q_E terms to latent heat flux, the Q_M terms to heat associated with melting or freezing of water, and the Q_I terms to changes in heat storage caused by conduction or redistribution of water. The P terms refer to precipitation, the E terms to evaporation, the R terms to runoff and the A terms to water transferred between different components of the landscape. The subscript 1 refers to the first soil layer, and j to a generalized other layer.

Finally, each change in energy or moisture storage is compared in turn with the corresponding net flux of energy or moisture, and if the difference is greater than a selected threshold value, an error message is printed out and the

run is stopped.

6.23.1 Detailed Description

Central module for all competition scheme-related operations.

Competition between PFTs in CTEM is based upon modified L–V equations [Arora2006-pp] [Arora2006-ax]. The L–V equations [Lotka1925elements] [Volterra1926-iz] have been adapted from their initial application for simulating predator–prey interactions in ecosystem models as described below.

Competition parametrization

The change in fractional coverage (f) of a PFT α through time, $\frac{df_\alpha}{dt}$, is expressed as the result of mortality, and competition and colonization (CC) interactions with the other PFTs present in a grid cell and bare ground, collectively represented as B where $\alpha \notin B$:

$$\frac{df_\alpha}{dt} = g(f_\alpha, f_B) - m_\alpha f_\alpha.$$

The CC interactions are represented symbolically by the $g(f_\alpha, f_B)$ function. Mortality is assumed to be proportional to the number density of plants and represented by the mortality term, $m_\alpha f_\alpha$. The PFT-dependent mortality rate (m_α ; day^{-1}) (described further in Sect. mort) produces bare ground via a number of processes, and that bare

ground is subsequently available for colonization. We consider the fractional coverage for N PFTs plus bare ground ($f_{N+1} = f_{bare}$) where $\sum_{j=1}^{N+1} f_j = 1$. For competition between unequal competitors, the PFTs are ranked in terms of their dominance. If PFT α is the most dominant, it will invade the area of other PFTs and the bare ground ($f_B, \alpha \notin B$). Woody PFTs are all more dominant than grass PFTs since trees can successfully invade grasses by overshading them [Siemann2003-jl] and thus are ranked higher. Within tree or grass PFTs the dominance rank of a PFT is calculated based upon its colonization rate ($c_\alpha; day^{-1}$) with higher colonization rates giving a higher dominance ranking. For the general case of PFT α with a dominance rank of i , we describe the ranking from most dominant to least as $1, 2, \dots, i-1, i, i+1, \dots, N$. Equation (concepteqn) can then be reformulated following a phenomenological approach as

$$\frac{df_\alpha}{dt} = f_\alpha^b (c_{\alpha,i+1} f_{i+1} + c_{\alpha,i+2} f_{i+2} + \dots + c_{\alpha,N} f_N) - f_\alpha (c_{1,\alpha} f_1^b + c_{2,\alpha} f_2^b + \dots + c_{(i-1),\alpha} f_{i-1}^b) - m_\alpha f_\alpha,$$

where the exponent b is an empirical parameter, which controls the behaviour of the L–V equations. In the original L–V formulation, b is 1, but we modify the L–V relations by using $b = 0$ following [Arora2006-pp] [Arora2006-ax] (implications of this choice are expanded upon below). The fractional cover of PFT α then changes depending on the gains it makes into the area of less dominant PFTs and the losses it suffers due to mortality and encroachment by more dominant PFTs. The rate of change of the bare fraction, f_{bare} , is expressed as

$$\frac{df_{bare}}{dt} = \sum_{\beta=1}^N (m_\beta f_\beta - c_{\beta,bare} f_\beta^b f_{bare}).$$

The rate at which PFT α invades another PFT β is given by

$$c_{\alpha,\beta} f_\alpha^b f_\beta = c_\alpha \left(\frac{c_{\alpha,\beta}}{c_\alpha} \right) f_\alpha^b f_\beta = c_\alpha \delta_{\alpha,\beta} f_\alpha^b f_\beta.$$

A PFT invading bare ground has an unimpeded invasion rate, c_α . The ratio of the invasion rate by PFT α into area covered by another PFT β and its unimpeded invasion rate ($\frac{c_{\alpha,\beta}}{c_\alpha}$) gives the relative efficiency of colonization, termed $\delta_{\alpha,\beta}$, which is a scalar between 0 and 1. δ is 1 for invasion of any PFT into bare ground and 1 for tree PFT invasion into grass PFTs. If a PFT β has a lower dominance ranking than another PFT α then $\delta_{\beta,\alpha} = 0$ implying that sub-dominant PFTs do not invade dominant PFTs, but get invaded by them, i.e. $\delta_{\alpha,\beta} = 1$. Equation (full) can then be written more succinctly for each PFT as

$$\frac{df_\alpha}{dt} = \sum_{\beta=1}^{N+1} (c_\alpha \delta_{\alpha,\beta} f_\alpha^b f_\beta - c_\beta \delta_{\beta,\alpha} f_\alpha f_\beta^b) - m_\alpha f_\alpha.$$

The value of parameter b is related to the manner in which two PFTs interact, represented by $f_\alpha^b f_\beta$, in Eqs. (full)–(coloniz)}. As a result, the value of b affects the equilibrium solution for fractional coverage of PFTs as well as how f_i evolves over time.

For the usual form of the L–V equations with $b = \delta = 1$, and for the case of a grid cell with two PFTs, the competition–colonization equations are

$$\frac{df_1}{dt} = c_1 f_1 (f_2 + f_{bare}) - m_1 f_1 = c_1 f_1 (1 - f_1) - m_1 f_1, \quad \frac{df_2}{dt} = c_2 f_2 f_{bare} - c_1 f_1 f_2 - m_2 f_2 = c_2 f_2 (1 - f_1 - f_2) - c_1 f_1 f_2 - m_2 f_2,$$

where the dominant PFT 1 invades PFT 2 and the bare fraction, and PFT 2 invades only the bare fraction. The equilibrium solutions for f_1 and f_2 in this case are

$$f_1 = \max \left[\frac{c_1 - m_1}{c_1}, 0 \right],$$

$$f_2 = \max \left[\frac{c_2 - c_2 f_1 - c_1 f_1 - m_2}{c_2}, 0 \right] = \max \left[\frac{(c_2 - m_2) - (1 + \frac{c_2}{c_1})(c_1 - m_1)}{c_2}, 0 \right],$$

In Eq. (f2_eq_b_eq_1)), as long as $(c_1 - m_1) > (c_2 - m_2)$ the equilibrium solution for f_2 will always be zero and coexistence is not possible.

For $b = 0$ and $\delta = 1$, the competition–colonization equations are

$$\frac{df_1}{dt} = c_1(f_2 + f_{bare}) - m_1 f_1 = c_1(1 - f_1) - m_1 f_1, \quad \frac{df_2}{dt} = c_2 f_{bare} - c_1 f_2 - m_2 f_2 = c_2(1 - f_1 - f_2) - c_1 f_2 - m_2 f_2,$$

and the corresponding equilibrium fractions are

$$f_1 = \frac{c_1}{c_1 + m_1},$$

$$f_2 = \frac{c_2(1 - f_1)}{(c_1 + c_2 + m_2)}.$$

In Eqs. (f_equl_b_eq_0_1)) and (f_equl_b_eq_0_2)), as long as $m_1 > 0$ and $c_2 > 0$, then PFT 2 will always exist and equilibrium coexistence is possible. Values of parameter b between 1 and 0 yield equilibrium values of f_2 that vary between 0 (Eq. f2_eq_b_eq_1)) and those obtained using Eq. (f_equl_b_eq_0_2)). $b = 0$ yields a maximum value of equilibrium f_2 allowing PFT 2 to coexist maximally.

In the standard L–V equations for predator–prey interactions coexistence is possible because the predator depends on prey for its food and so the predator population suffers as the prey population declines. This is in contrast to the application of the equations for competition between PFTs where the dominant PFT does not depend on sub-dominant PFTs for its existence and is thus able to exclude them completely. The PFTs interact with each other through the invasion term $(-c_{\beta}\delta_{\beta,\alpha}f_{\alpha}f_{\beta}^b)$ in Eq. (compact)), where $\delta_{\alpha,\beta} = 1$ or 0 depending on whether PFT α can or cannot invade PFT β , respectively, as mentioned earlier. This interaction through invasion is represented by $-c_1 f_1 f_2$ in Eq. (cc_eq_b_eq_1_2)) (for $b = 1$) and by $-c_1 f_2$ in Eq. (cc_eq_b_eq_0_1)) (for $b = 0$). The magnitude of this interaction thus depends on the value of parameter b . When $b=1$ the interaction is proportional to the product of the fractional coverage of the two PFTs ($f_1 f_2$). When $b = 0$, the interaction is proportional to the fractional coverage of the PFT being invaded (f_2). The use of $b = 0$ thus reduces the product term $f_{\alpha}^b f_{\beta}$ to f_{β} and implies that the invasion of sub-dominant PFT β does not depend on the current fractional coverage of the dominant PFT α . This case may be thought of as corresponding to the general availability of the seeds of the dominant PFT α that may germinate and invade the coverage of the sub-dominant PFT β provided the climate is favourable, even if PFT α does not exist in the grid cell, i.e. $f_{\alpha} = 0$ (in the case where $f_{\alpha} = 0$, the PFT is always assumed to have a dormant seed bank in the grid cell given the long lifetimes of seeds and their wide dispersion). In contrast, in the standard version of the L–V equations, as implemented for predator–prey interactions, b always equals 1 since the amount of predation, and hence the reduction in the number of prey, depends on the product of the number of predators and the number of prey. Using $b = 0$ is thus consistent with invasion of the sub-dominant PFT β being unaffected by the fractional coverage of the dominant PFT α .

Colonization rate

The PFT-dependent colonization rate (c_{α} ; day^{-1}) is calculated based on the fraction (Λ_{α}) of positive NPP ($kg C m^{-2} day^{-1}$) that is used for spatial expansion

$$c_{\alpha} = \Lambda_{\alpha} NPP_{\alpha} \xi_{\alpha},$$

where ξ_{α} ($(kg C)^{-1} m^2$) is the inverse sapling density calculated as the reciprocal of vegetation biomass ($C_{veg,\alpha}$; $kg C m^{-2}$) multiplied by a PFT-dependent constant ($S_{sap,\alpha}$; unitless; see also [ctem_params.f90](#))

$$\xi_{\alpha} = \frac{1}{S_{sap,\alpha} \max[0.25, \min(5.0, C_{veg,\alpha})]}.$$

The fraction of NPP used for spatial expansion, Λ_{α} , is calculated using the leaf area index (LAI_{α} ; $m^2 leaf (m^2 ground)^{-1}$) of a PFT

$$\Lambda_{\alpha} = \min(\lambda_{max}, \max(\lambda_{1,\alpha}, \lambda_{2,\alpha})),$$

$$if LAI_{\alpha} \leq LAI_{min,\alpha} : \quad \lambda_{1,\alpha} = 0 \quad if LAI_{min,\alpha} < LAI_{\alpha} < LAI_{max,\alpha} : \quad \lambda_{1,\alpha} = \frac{LAI_{\alpha} - LAI_{min,\alpha}}{LAI_{max,\alpha} - LAI_{min,\alpha}} \lambda_{max} \quad if LAI_{\alpha} \geq LAI_{max,\alpha} : \quad \lambda_{1,\alpha} = \lambda_{max}$$

$$if LAI_{\alpha} > 0.25LAI_{min,\alpha} : \lambda_{2,\alpha} = \cosh(0.115(LAI_{\alpha} - 0.25LAI_{min,\alpha})) - 1 if LAI_{\alpha} \leq 0.25LAI_{min,\alpha} : \lambda_{2,\alpha} = 0$$

The original formulation of [Arora2006-pp] only considered $\lambda_{1,\alpha}$ but here we adjust the parametrization with the addition of $\lambda_{2,\alpha}$, which ensures that a small fraction of NPP is used for spatial expansion even at very low LAI_{α} values. This additional constraint allows for improved fractional coverage of grasses in arid regions. Similar to $S_{sap,\alpha}$, $LAI_{min,\alpha}$ and $LAI_{max,\alpha}$ are PFT-dependent parameters (see also [ctem_params.f90](#)).

The value of λ_{max} is set to 0.1 so that a maximum of 10\% of daily NPP can be used for spatial expansion. Finally, Λ_{α} is set to zero for tree PFTs when they are in a full leaf-out mode and all NPP is being used for leaf expansion (see Appendix phenol)).

Parameters

<i>nml</i>	total number of mosaic tiles with pft fractions larger than 1, see gatprep.f
<i>ilmos</i>	indices for scattering, see gatprep.f
<i>jmos</i>	indices for scattering, see gatprep.f
<i>fare_cmp</i>	fractional coverage of ctem's 10 pfts in each latitudinal grid cell
<i>nppveg_cmp</i>	npp for each pft type of vegetated area in each latitudinal grid cell
<i>geremort_cmp</i>	growth related mortality in each latitudinal grid cell
<i>intrmort_cmp</i>	intrinsic (age related) mortality in each latitudinal grid cell
<i>gleafmas_cmp</i>	green leaf mass for each of the 10 ctem pfts in each latitudinal grid cell
<i>bleafmas_cmp</i>	brown leaf mass for each of the 10 ctem pfts in each latitudinal grid cell
<i>stemmass_cmp</i>	stem mass for each of the 10 ctem pfts in each latitudinal grid cell
<i>rootmass_cmp</i>	root mass for each of the 10 ctem pfts in each latitudinal grid cell
<i>litrmass_cmp</i>	litter mass for each of the 10 ctem pfts + bare, in each latitudinal grid cell
<i>soilcmass_cmp</i>	soil carbon mass for each of the 10 ctem pfts + bare, in each latitudinal grid cell
<i>lambda_cmp</i>	fraction of npp that is used for horizontal expansion in each latitudinal grid cell
<i>bmasveg_cmp</i>	total (gleaf + stem + root) biomass for each ctem pft, kgc/m^2 in each latitudinal grid cell
<i>burnvegf_cmp</i>	fractional areas burned, for ctem pfts in each latitudinal grid cell
<i>add2allo_cmp</i>	npp $kgc/m^2.day$ in each latitudinal grid cell that is used for expansion and subsequently allocated to leaves, stem, and root via the allocation part of the model.
<i>cc_cmp</i>	colonization rate & mortality rate in each latitudinal grid cell
<i>mm_cmp</i>	colonization rate & mortality rate in each latitudinal grid cell
<i>fcanmx_cmp</i>	fractional coverage of class' 4 pfts in each latitudinal grid cell
<i>grclarea_cmp</i>	area of the grid cell, km^2
<i>vgbiomas_cmp</i>	grid averaged vegetation biomass, kgc/m^2
<i>gavgltms_cmp</i>	grid averaged litter mass, kgc/m^2
<i>gavgscms_cmp</i>	grid averaged soil c mass, kgc/m^2
<i>lucemcom_cmp</i>	land use change (luc) related combustion emission losses in each latitudinal grid cell, u-mol $co_2/m^2.sec$
<i>lucitrin_cmp</i>	luc related inputs to litter pool, in each latitudinal grid cell, u-mol $co_2/m^2.sec$
<i>lucsocin_cmp</i>	luc related inputs to soil c pool, in each latitudinal grid cell, u-mol $co_2/m^2.sec$
<i>pfcancmx_cmp</i>	previous year's fractional coverages of pfts in each latitudinal grid cell
<i>nfcancmx_cmp</i>	next year's fractional coverages of pfts in each latitudinal grid cell
<i>pstemmass_cmp</i>	stem mass from previous timestep, is value before fire. used by burntobare subroutine
<i>pgleafmass_cmp</i>	root mass from previous timestep, is value before fire. used by burntobare subroutine
<i>pftexist_cmp</i>	logical array indicating pfts exist (t) or not (f) in each latitudinal grid cell
<i>ta_cmp</i>	mean daily temperature (k) in each latitudinal grid cell
<i>precip_cmp</i>	daily precipitation (mm/day) in each latitudinal grid cell
<i>netrad_cmp</i>	daily net radiation (w/m2) in each latitudinal grid cell
<i>tcurm_cmp</i>	temperature of the current month (c) in each latitudinal grid cell
<i>srpcuryr_cmp</i>	water surplus for the current year in each latitudinal grid cell
<i>dftcuryr_cmp</i>	water deficit for the current year in each latitudinal grid cell
<i>tmonth_cmp</i>	monthly temperatures in each latitudinal grid cell
<i>anpcpcur_cmp</i>	annual precipitation for current year (mm) in each latitudinal grid cell
<i>anpecur_cmp</i>	annual potential evaporation for current year (mm) in each latitudinal grid cell
<i>gdd5cur_cmp</i>	growing degree days above 5 c for current year in each latitudinal grid cell

<i>surmncur_cmp</i>	number of months with surplus water for current year in each latitudinal grid cell
<i>defmncur_cmp</i>	number of months with water deficit for current year in each latitudinal grid cell
<i>srplscur_cmp</i>	water surplus for the current month in each latitudinal grid cell
<i>defctcur_cmp</i>	water deficit for the current month in each latitudinal grid cell
<i>twarmm_cmp</i>	temperature of the warmest month (c) in each latitudinal grid cell
<i>tcoldm_cmp</i>	temperature of the coldest month (c) in each latitudinal grid cell
<i>gdd5_cmp</i>	growing degree days above 5 c in each latitudinal grid cell
<i>aridity_cmp</i>	aridity index, ratio of potential evaporation to precipitation in each latitudinal grid cell
<i>srplsmon_cmp</i>	number of months in a year with surplus water i.e. precipitation more than potential evaporation in each latitudinal grid cell
<i>defctmon_cmp</i>	number of months in a year with water deficit i.e. precipitation less than potential evaporation in each latitudinal grid cell
<i>anndefct_cmp</i>	annual water deficit (mm) in each latitudinal grid cell
<i>annsrpls_cmp</i>	annual water surplus (mm) in each latitudinal grid cell
<i>annpcp_cmp</i>	annual precipitation (mm) in each latitudinal grid cell
<i>dry_season_↔ length_cmp</i>	length of dry season (months) in each latitudinal grid cell

parameters used

note the structure of parameter vectors which clearly shows the class pfts (along rows) and ctem sub-pfts (along columns)

needle leaf	evg1	evg2	dcd
broad leaf	evg	dcd-cld	dcd-dry
crops	c3	c4	—
grasses	c3	c4	—

initialization

note that netradrow is not initialized here because it is updated

unmapping the pft fraction in each grid cell (*fare_cmp*) back to the pft index in each mosaic of each grid cell (*fcancmxrow*) and update the pft areal fraction in each mosaic of each grid cell (*farerow*)

check if bare fraction is existed

unmapping back to *fcancmxrow* and update *farerow*

gathering the pft index in each mosaic of each grid cell (*fcancmxrow*) to the pft index in each mosaic (*fcancmx*) nml, *ilmos* and *jlmos* are referring to *gatprep.f*

6.25.1 Detailed Description

Principle driver for CTEM.

The basic model structure of CTEM includes three live vegetation components (leaf (L), stem (S) and root (R)) and two dead carbon pools (litter or detritus (D) and soil carbon (H)). The amount of carbon in these pools (C_L , C_S , C_R , C_D , C_H , $kgCm^{-2}$) is tracked prognostically through the fluxes in and out of them. The rate change equations for carbon in these pools are summarized in Sect. `rate_change_eqns` after the processes leading to the calculation of fluxes in and out of these pools are introduced in the following sections.

6.25.2 Function/Subroutine Documentation

6.25.2.1 subroutine `ctem` (`real`, dimension(`ilg,icc`), intent(inout) `fcancmx`, `real`, dimension(`ilg`), intent(in) `fsnow`, `real`, dimension(`ilg,ignd`), intent(in) `sand`, `real`, dimension(`ilg,ignd`), intent(in) `clay`, `integer`, intent(in) `il1`, `integer`, intent(in) `il2`, `integer`, intent(in) `iday`, `real`, dimension(`ilg`), intent(in) `radj`, `real`, dimension(`ilg`), intent(in) `tcano`, `real`, dimension(`ilg`), intent(in) `tcans`, `real`, dimension(`ilg,ignd`), intent(in) `tbarc`, `real`, dimension(`ilg,ignd`), intent(in) `tbarcs`, `real`, dimension(`ilg,ignd`), intent(in) `tbarg`, `real`, dimension(`ilg,ignd`), intent(in) `tbargs`, `real`, dimension(`ilg`), intent(in) `ta`, `real`, dimension(`ilg,ignd`), intent(in) `delzw`, `real`, dimension(`ilg,icc`), intent(inout) `ancsveg`, `real`, dimension(`ilg,icc`), intent(inout) `ancgveg`, `real`, dimension(`ilg,icc`), intent(inout) `rmlcsveg`, `real`, dimension(`ilg,icc`), intent(inout) `rmlcgveg`, `real`, dimension(`ilg,ignd`), intent(in) `zbotw`, `real`, dimension(`ilg,ignd`), intent(in) `thliqc`, `real`, dimension(`ilg,ignd`), intent(in) `thliqg`, `real`, intent(in) `deltat`, `real`, dimension(`ilg`), intent(in) `uwind`, `real`, dimension(`ilg`), intent(in) `vwind`, `real`, dimension(`ilg`), intent(in) `lightng`, `real`, dimension(`ilg`), intent(in) `prbfrhuc`, `real`, dimension(`ilg`), intent(inout) `extnprob`, `integer`, dimension(`ilg`), intent(in) `stdaln`, `real`, dimension(`ilg,ignd`), intent(in) `tbar`, `logical`, intent(inout) `transientPOPD`, `integer`, dimension(`ican`) `no2pfts`, `real`, dimension(`ilg,icc`), intent(in) `pfcancmx`, `real`, dimension(`ilg,icc`), intent(in) `nfcancmx`, `logical`, intent(in) `Induseon`, `real`, dimension(`ilg,ignd`), intent(in) `thicec`, `real`, dimension(`ilg`), intent(in) `soildpth`, `integer`, intent(in) `spinfast`, `real`, dimension(`ilg,icc`), intent(in) `todfrac`, `logical`, intent(in) `PFTCompetition`, `real`, dimension(`ilg`), intent(in) `netrad`, `real`, dimension(`ilg`), intent(in) `precip`, `real`, dimension(`ilg,ignd`), intent(in) `psisat`, `real`, dimension(`ilg`), intent(in) `grclarea`, `real`, dimension(`ilg`), intent(inout) `popdin`, `logical`, intent(in) `dofire`, `logical`, intent(in) `dowetlands`, `logical`, intent(in) `obswetf`, `integer`, dimension(`ilg,ignd`), intent(in) `isand`, `real`, dimension(`ilg`), intent(in) `faregat`, `logical`, intent(in) `onetile_perPFT`, `real`, dimension(`ilg`), intent(in) `wetfrac`, `real`, dimension(`ilg,8`), intent(in) `slopefrac`, `real`, dimension(`ilg,ignd`), intent(in) `bi`, `real`, dimension(`ilg,ignd`), intent(in) `thpor`, `real`, dimension(`ilg,ignd`), intent(in) `thiceg`, `real`, dimension(`ilg`), intent(in) `currlat`, `real`, dimension(`ilg`), intent(in) `ch4conc`, `real`, intent(in) `GRAV`, `real`, intent(in) `RHOW`, `real`, intent(in) `RHOICE`, `logical`, intent(in) `leapnow`)

Parameters

<code>in</code>	<code>Induseon</code>	logical switch to run the land use change subroutine or not.
<code>in</code>	<code>pftcompetition</code>	logical boolean telling if competition between pfts is on or not
<code>in</code>	<code>dofire</code>	boolean, if true allow fire, if false no fire.
<code>in</code>	<code>dowetlands</code>	if true allow wetland methane emission
<code>in</code>	<code>obswetf</code>	if true, use read-in observed wetland fraction
<code>in</code>	<code>onetile_perpft</code>	if you are running with one tile per PFT in mosaic mode, set to true. Changes how competition is run. Specifically it allows competition between tiles. This is not recommended for any case where you don't have one PFT in each tile as it has not been tested for that.
<code>in</code>	<code>leapnow</code>	true if this year is a leap year. Only used if the switch 'leap' is true.
<code>in</code>	<code>iday</code>	day of year
<code>in</code>	<code>spinfast</code>	spinup factor for soil carbon whose default value is 1. as this factor increases the soil c pool will come into equilibrium faster. reasonable value for spinfast is between 5 and 10. when spinfast.ne.1 then the balcar subroutine is not run.

in	<i>il1</i>	il1=1
in	<i>il2</i>	il2=ilg (no. of grid cells in latitude circle)
in	<i>fsnow</i>	fraction of snow simulated by class
in	<i>sand</i>	percentage sand
in	<i>clay</i>	percentage clay
in	<i>radj</i>	latitude in radians
in	<i>tcano</i>	canopy temperature for canopy over ground subarea, K
in	<i>tcans</i>	canopy temperature for canopy over snow subarea, K
in	<i>tbar</i>	soil temperature, k
in	<i>tbarc</i>	soil temperature for canopy over ground subarea, K
in	<i>tbarcs</i>	soil temperature for canopy over snow subarea
in	<i>tbarg</i>	soil temperature for ground subarea
in	<i>tbargs</i>	soil temperature for snow over ground subarea
in	<i>psisat</i>	Saturated soil matric potential (m)
in	<i>bi</i>	Brooks and Corey/Clapp and Hornberger b term
in	<i>thpor</i>	Soil total porosity ($cm^3 cm^{-3}$) - daily average
in	<i>ta</i>	air temp, K
in	<i>delzw</i>	thicknesses of the soil layers
in	<i>zbotw</i>	bottom of soil layers
in	<i>soildpth</i>	soil depth (m)
in	<i>thliqc</i>	liquid mois. content of soil layers, for canopy over snow and canopy over ground subareas
in	<i>thliqg</i>	liquid mois. content of soil layers, for ground and snow over ground subareas
in	<i>thicec</i>	Frozen soil moisture content for canopy over snow and canopy over ground subareas
in	<i>thiceg</i>	Frozen soil moisture content for ground and snow over ground subareas
in	<i>deltat</i>	CTEM timestep in days
in	<i>grclarea</i>	area of the grid cell, km^2
in	<i>currlat</i>	centre latitude of grid cells in degrees
in	<i>uwind</i>	u wind speed, m/s
in	<i>vwind</i>	v wind speed, m/s
in	<i>precip</i>	daily precipitation (mm/day)
in	<i>netrad</i>	daily net radiation (w/m2)
in	<i>lightng</i>	total lightning frequency, flashes/km2.year
in	<i>prbfrhuc</i>	probability of fire due to human causes
in	<i>pfcancmx</i>	previous year's fractional coverages of pfts
in	<i>nfcancmx</i>	next year's fractional coverages of pfts
in	<i>todfrac</i>	max. fractional coverage of ctem's 9 pfts by the end of the day, for use by land use subroutine
in	<i>ch4conc</i>	Atmospheric CH_4 concentration at the soil surface (ppmv)
in	<i>stdaln</i>	an integer telling if ctem is operated within gcm (=0) or in stand alone mode (=1). this is used for fire purposes. see comments just above where disturb subroutine is called.
in	<i>grav</i>	Acceleration due to gravity ($m s^{-1}$), (CLASS param) passed in to avoid the common block structure.
in	<i>rhow</i>	Density of water ($kg m^{-3}$), (CLASS param) passed in to avoid the common block structure.
in	<i>rhoice</i>	Density of ice ($kg m^{-3}$), (CLASS param) passed in to avoid the common block structure.

in, out	<i>transientpopd</i>	if set true use population density data to calculate fire extinguishing probability and probability of fire due to human causes, or if false, read directly from .ctm file
in, out	<i>ancsveg</i>	net photosynthetic rate for ctems 9 pfts for canopy over snow subarea
in, out	<i>ancgveg</i>	net photosynthetic rate for ctems 9 pfts for canopy over ground subarea
in, out	<i>rmlcsveg</i>	leaf respiration rate for ctems 9 pfts for canopy over snow subarea
in, out	<i>rmlcgveg</i>	leaf respiration rate for ctems 9 pfts for canopy over ground subarea
in, out	<i>extnprob</i>	fire extinguishing probability
in, out	<i>fcancmx</i>	max. fractional coverage of ctem's 9 pfts, but this can be modified by land-use change, and competition between pfts
in, out	<i>popdin</i>	population density (<i>people/km²</i>)
	<i>nol2pfts</i>	number of level 2 ctem pfts

Constants and parameters are located in [ctem_params.f90](#)

Begin calculations

Generate the sort index for correspondence between 9 pfts and the 12 values in the parameter vectors

If you intend to have competition and LUC between tiles then set onetile_perPFT to true. NOTE: Turning onetile_perPFT to true is usually not the behaviour desired unless you are running with one PFT on each tile and want them to compete for space across tiles. So in general keep this as False. JM Jan 2016.

this is composite/mosaic mode (in mosaic competition only occurs WITHIN a tile)

Calculate bioclimatic parameters for estimating pfts existence

If first day of year then based on updated bioclimatic parameters find if pfts can exist or not. If .not. inibioclim then it is the first year of a run that you do not have the climatological means already in the CTM file. After one year inibioclim is set to true and the climatological means are used from the first year.

Call competition subroutine which on the basis of previous day's npp estimates changes in fractional coverage of pfts

If landuse is on, then implement luc, change fractional coverages, move biomasses around, and estimate luc related combustion emission losses.

Land use change and competition for mosaics needs mapping and unmapping of the pfts. Composite does not require these extra steps.

Check if number of mosaics is equal to the number of pfts plus one bare, e.g., nmos=iccp1

check for fcancmx(i,j). this should be either 0 or 1 for competition to work.

competition_map scatters and maps the array with indices of (ilg,icc) to (nlat,icc) for preparation for competition

Calculate bioclimatic parameters for estimating pfts existence

If first day of year then based on updated bioclimatic parameters find if pfts can exist or not. If .not. inibioclim then it is the first year of a run that you do not have the climatological means already in the CTM file. After one year inibioclim is set to true and the climatological means are used from the first year.

call competition subroutine which on the basis of previous day's npp estimates changes in fractional coverage of pfts

Competition_unmap unmaps and gathers the array with indices (nlat,icc) back to (ilg,icc) after competition is done

initialize required arrays to zero

Store green and brown leaf, stem, and root biomass, and litter and soil c pool mass in arrays. knowing initial sizes of all pools and final sizes at the end of this subroutine, we check for conservation of mass.

Initialization ends

Find fc and fcs based on fcancmx

Autotrophic respiration

Leaf respiration is calculated in phtsyn subroutine, while stem and root maintenance respiration are calculated here.

We treat canopy over ground and canopy over snow subareas separately because stem temperature (for which we use canopy temperature as a surrogate) can be different for these two subareas.

Find maintenance respiration for canopy over snow sub-area in $\mu\text{mol CO}_2/\text{m}^2/\text{sec}$

Find maintenance respiration for canopy over ground sub-area

If aileg/gleafmas is zero, i.e. real leaves are not on, then make maintenance respiration and gpp from storage/imaginary lai equal to zero so that we don't use these numbers in carbon budget.

Find vegetation averaged leaf, stem, and root respiration, and gpp using values from canopy over ground and canopy over snow subareas

Now that we know maintenance respiration from leaf, stem, and root and gpp, we can find growth respiration for each vegetation

Calculate grid/tile-averaged rates of rm, rg, npp, and gpp

Add moss GPP and rml to the grid/tile average C fluxes

Heterotrophic respiration part starts

Find heterotrophic respiration rates for canopy over ground subarea

Find heterotrophic respiration rates from bare ground subarea

Find heterotrophic respiration rates from snow over ground subarea

When peatlands are simulated find the peat heterotrophic respiration

Find vegetation averaged litter and soil c respiration rates using values from canopy over ground and canopy over snow subareas

Find litter and soil c respiration rates averaged over the bare fraction of the grid cell using values from ground and snow over ground sub-areas.

Find grid averaged litter and soil c respiration rates

add moss and peat soil respiration to the grid

In loop 360/370 we have aggregated across all pfts for litres and socres, In loop 380 we add bareground (iccp1) values to the grid sum if it's not peatland. If it is a peatland, we add litresmoss to the grid sum but no bareground values as we assume peatlands have no bareground.

Update the litter and soil c pools based on litter and soil c respiration rates found above. also transfer humidified litter to the soil c pool.

Convert $\mu\text{mol CO}_2/\text{m}^2.\text{sec} \rightarrow \text{kgC}/\text{m}^2$ respired over the model time step

Update litter and soil c pools

Next we add bareground litter mass and humification for non-peatlands. In peatlands there is no bareground litter mass since it is the moss layer.

Estimate soil respiration. this is sum of heterotrophic respiration and root maintenance respiration.

But over the bare fraction there is no live root.

Find grid averaged humification and soil respiration rates

After aggregation of humification and soil respiration rates for non-peatlands

to the grid/tile level, the same must be done for bareground (iccp1). For peatlands, we additionally add moss values to the grid (litter respiration and moss root respiration). Note in loop 430 iccp1 is passed for peatlands

Find CH₄ wetland area (if not prescribed) and emissions:

Calculate the methane that is oxidized by the soil sink

Estimate allocation fractions for leaf, stem, and root components.

Estimate fraction of npp that is to be used for horizontal expansion (lambda) during the next day (i.e. this will be determining the colonization rate in competition).

We use the following new function to smooth the transition for lambda as an abrupt linear increase does not give good results. JM Jun 2014

If tree and leaves still coming out, or if npp is negative, then do not expand

Maintenance respiration also reduces leaf, stem, and root biomass. when npp for a given pft is positive then this is taken care by allocating +ve npp amongst the leaves, stem, and root component. when npp for a given pft is negative then maintenance respiration loss is explicitly deducted from each component.

Convert npp and maintenance respiration from different components from units of $\mu\text{mol CO}_2/\text{m}^2.\text{sec}$ -> kgC/m^2 sequestered or respired over the model time step (deltat)

Remove the cost of making reproductive tissues. This cost can only be removed when NPP is positive.

i.e. if lfstatus.eq.4 and since we do not have any real leaves on then we do not take into account CO_2 uptake by imaginary leaves in carbon budget. rmlvgstp(i,j) should be zero because we set maintenance respiration from storage/imaginary leaves equal to zero. in loop 180

since no real leaves are on, make allocation fractions equal to zero.

convert net change in leaf, stem, and root biomass into $\mu\text{mol CO}_2/\text{m}^2.\text{sec}$ for use in balcar subroutine

to avoid over/underflow problems set gleafmas, stemmass, and rootmass to zero if they get too small

calculate grid averaged value of C related to spatial expansion

Phenology part starts

the phenology subroutine determines leaf status for each pft and calculates leaf litter. the phenology subroutine uses soil temperature (tbar) and root temperature. however, since ctem doesn't make the distinction between canopy over ground, and canopy over snow sub-areas for phenology purposes (for example, leaf onset is not assumed to occur at different times over these sub-areas) we use average soil and root temperature in the phenology subroutine.

calculate average soil temperature and root temperature using values for canopy over ground and canopy over snow sub-areas, for each vegetation type.

Call the phenology subroutine, which determines the leaf growth status, calculates leaf litter, and converts green grass into brown.

while leaf litter is calculated in the phenology subroutine, stem and root turnover is calculated in the turnover subroutine.

Update green leaf biomass for trees and crops and brown leaf biomass for grasses

Update stem and root biomass for litter deductions

Update litter pool with leaf litter calculated in the phenology subroutine and stem and root litter calculated in the turnover subroutine. Also add the reproduction carbon directly to the litter pool

Call the mortality subroutine which calculates mortality due to reduced growth and aging. exogenous mortality due to fire and other disturbances and the subsequent litter that is generated is calculated in the disturb subroutine.

set maxage >0 in [ctem_params.f90](#) to switch on mortality due to age and reduced growth. Mortality is linked to the competition parameterization and generates bare fraction.

Update leaf, stem, and root biomass pools to take into loss due to mortality, and put the litter into the litter pool. the mortality for green grasses doesn't generate litter, instead they turn brown.

call the disturbance subroutine which calculates mortality due to fire and other disturbances. the primary output from from disturbance subroutine is litter generated, c emissions due to fire and area burned, which may be used to estimate change in fractional coverages.

disturbance is spatial and requires area of gcm grid cell and areas of different pfts present in a given grid cell. however, when ctem is operated at a point scale then it is assumed that the spatial scale is 1 hectare = 10,000 m^2 . the disturbance subroutine may be stopped from simulating any fire by specifying fire extinguishing probability equal to 1.

Calculate nbp (net biome production) for each pft by taking into account C emission losses. The disturbance routine produces emissions due to fire and it also calculates emissions due to LUC. These LUC carbon emissions due to combustion associated with LUC are first estimated in LUC. This flux is spread out over the whole year and is therefore subtracted to get NBP of each pft as well as the grid averaged value of NBP. Also LUC related combustion flux is assumed to be spread uniformly over the grid cell and thus reduces NBP of each PFT

Calculate grid. averaged rate of carbon emissions due to fire in u-mol co2/m2.sec. convert all emission losses from kgc/m^2 emitted in 1 day to u-mol co2/m2.sec. calculate grid averaged carbon emission losses from litter.

calculate total litter fall from each component (leaves, stem, and root) from all causes (normal turnover, drought and cold stress for leaves, mortality, and disturbance) for use in balcar subroutine

units here are $kgc/m^2.day$

convert units to u-mol co2/m2.sec

calculate grid-average vegetation biomass, litter mass, and soil carbon mass, and litter fall rate

Add the bare ground values to the grid-average. If a peatland, we assume no bareground and add the moss values instead. Note: peatland soil C is not aggregated from plants but updated by humification and respiration from the previous stored value

At this stage we have all required fluxes in u-mol co2/m2.sec and initial (loop 140 and 145) and updated sizes of all pools (in kgc/m^2). Now we call the balcar subroutine and make sure that C in leaves, stem, root, litter and soil C pool balances within a certain tolerance.

Finally find vegetation structural attributes which can be passed to the land surface scheme using leaf, stem, and root biomass.

Calculation of gavglai is moved from loop 1100 to here since ailcg is updated by bio2str

6.26 src/ctem_params.f90 File Reference

This module holds CTEM globally accessible parameters. These parameters are used in all CTEM subroutines via use statements pointing to this module EXCEPT [PHTSYN3.f](#) which has the information passed in via arguments. This is a legacy thing.

Functions/Subroutines

- subroutine, public **ctem_params::prepareglobalparams**
- subroutine, public **ctem_params::allocateparamsctem** ()
- subroutine, public **ctem_params::readin_params**

Variables

- real, dimension(:), allocatable, parameter **ctem_params::zero** = 1.0e-20
- real, parameter **ctem_params::abszero** = 1e-12
this one is for runclassctem.f and [allocate.f](#)
- real, parameter **ctem_params::pi** = 3.1415926535898d0
- real, parameter **ctem_params::earthrad** = 6371.22
radius of earth, km
- real, parameter **ctem_params::km2tom2** = 1.0e+06
changes from km^2 to m^2
- real, parameter **ctem_params::deltat** = 1.0
CTEM's time step in days.
- integer, dimension(12) **ctem_params::monthdays** = [31,28,31,30,31,30,31,31,30,31,30,31]
days in each month

- integer, dimension(13) **ctem_params::monthend** = [0,31,59,90,120,151,181,212,243,273,304,334,365]
calender day at end of each month
- integer, dimension(12) **ctem_params::mmday** = [16,46,75,106,136,167,197,228,259,289,320,350]
mid-month day
- integer, parameter **ctem_params::nmon** = 12
Number of months in a year.
- integer **ctem_params::nlat**
Number of cells we are running, read in from the initialization file. Offline this always 1.
- integer **ctem_params::nmos**
Number of mosaic tiles, read in from the initialization file.
- integer **ctem_params::ilg**
nlat x nmos
- integer **ctem_params::ignd**
Number of soil layers, read in from the initialization file.
- integer **ctem_params::ican**
- integer **ctem_params::icp1**
- integer **ctem_params::icc**
- integer **ctem_params::iccp1**
- integer **ctem_params::l2max**
- integer **ctem_params::kk**
product of class pfts and l2max
- integer **ctem_params::numcrops**
number of crop pfts
- integer **ctem_params::numtreepfts**
number of tree pfts
- integer **ctem_params::numgrass**
number of grass pfts
- integer **ctem_params::numshrubs**
number of shrubs pfts
- logical, dimension(:), allocatable **ctem_params::crop**
simple crop matrix, define the number and position of the crops (NOTE: dimension icc)
- logical, dimension(:), allocatable **ctem_params::grass**
simple grass matrix, define the number and position of grass
- integer, dimension(3) **ctem_params::grass_ind** = [10, 11,12]
index of the grass pfts (3 grass pfts at present) !FLAG FLAG get rid of this!
- real, parameter **ctem_params::seed** = 0.001
seed pft fraction, same as in competition mosaic mode, all tiles are given this as a minimum
- real, parameter **ctem_params::minbare** = 1.0e-5
minimum bare fraction when running competition on to prevent numerical problems.
- real, parameter **ctem_params::c2dom** = 450.0
gc / kg dry organic matter factor from carbon to dry organic matter value is from Li et al. 2012 biogeosci
- real, parameter **ctem_params::wtch4** = 16.044
Molar mass of CH4 (\$g mol⁻¹){-1}\$)
- integer, parameter **ctem_params::nbs** = 4
- real **ctem_params::gasc** = 8.314
gas constant (\$J mol⁻¹ K⁻¹){-1}\$) !FLAG is there no global one I can use?
- real **ctem_params::tolrance** = 0.0001d0
our tolerance for balancing c budget in kg c/m2 in one day (differs when competition on or not)
- real **ctem_params::tolrnce1** = 0.5
kg c, tolerance of total c balance (FOR LUC) !FLAG would be good to make this consistent with global tolerance so only one value.

- logical **ctem_params::consallo** = .false.
Logical switch for using constant allocation factors (default value is false)
- integer, dimension(:), allocatable **ctem_params::modelpft**
Separation of pfts into level 1 (for class) and level 2 (for ctem) pfts.
- character(8), dimension(:), allocatable **ctem_params::pftlist**
List of PFTs.
- character(8), dimension(:), allocatable **ctem_params::vegtype**
Type of vegetation, options: Tree, Grass, Crop, Shrub.
- real, dimension(:), allocatable **ctem_params::kn**
Canopy light/nitrogen extinction coefficient; CAREFUL: Separate set defined in [PHTSYN3.f!](#)
- real, dimension(:), allocatable **ctem_params::omega**
omega, parameter used in allocation formulae (values differ if using prescribed vs. competition run)
- real, dimension(:), allocatable **ctem_params::epsilon_l**
Epsilon leaf, parameter used in allocation formulae (values differ if using prescribed vs. competition run)
- real, dimension(:), allocatable **ctem_params::epsilon_s**
Epsilon stem, parameter used in allocation formulae (values differ if using prescribed vs. competition run)
- real, dimension(:), allocatable **ctem_params::epsilon_r**
Epsilon root, parameter used in allocation formulae (values differ if using prescribed vs. competition run)
- real, dimension(:), allocatable **ctem_params::rtsrmin**
Minimum root:shoot ratio mostly for support and stability.
- real, dimension(:), allocatable **ctem_params::aldrifon**
Allocation to leaves during leaf onset.
- real, dimension(:), allocatable **ctem_params::caleaf**
Constant allocation fractions to leaves if not using dynamic allocation. (NOT thoroughly tested, and using dynamic allocation is preferable)
- real, dimension(:), allocatable **ctem_params::castem**
Constant allocation fractions to stem if not using dynamic allocation. (NOT thoroughly tested, and using dynamic allocation is preferable)
- real, dimension(:), allocatable **ctem_params::caroot**
Constant allocation fractions to roots if not using dynamic allocation. (NOT thoroughly tested, and using dynamic allocation is preferable)
- real, dimension(:), allocatable **ctem_params::abar**
parameter determining average root profile
- real, dimension(:), allocatable **ctem_params::avertmas**
average root biomass (kg c/m2) for ctem's 8 pfts used for estimating rooting profile
- real, dimension(:), allocatable **ctem_params::alpha**
parameter determining how the roots grow
- real, dimension(:), allocatable **ctem_params::prcnslai**
storage/imaginary lai is this percentage of maximum leaf area index that a given root+stem biomass can support
- real, dimension(:), allocatable **ctem_params::minslai**
minimum storage lai. this is what the model uses as lai when growing vegetation for scratch. consider these as model seeds.
- real, dimension(:), allocatable **ctem_params::mxrtdpth**
maximum rooting depth. this is used so that the rooting depths simulated by ctem's variable rooting depth parameterization are constrained to realistic values
- real, dimension(:), allocatable **ctem_params::albvis**
visible albedos of the ctem pfts
- real, dimension(:), allocatable **ctem_params::albnir**
near IR albedos of the 9 ctem pfts
- real, dimension(:), allocatable **ctem_params::tcoldmin**
minimum coldest month temperature
- real, dimension(:), allocatable **ctem_params::tcoldmax**

- maximum coldest month temperature*
- real, dimension(:), allocatable **ctem_params::twarmmax**
maximum warmest month temperature
- real, dimension(:), allocatable **ctem_params::gdd5lmt**
minimum gdd above 5 c required to exist
- real, dimension(:), allocatable **ctem_params::aridlmt**
aridity index limit for broadleaf drought/dry deciduous trees
- real, dimension(:), allocatable **ctem_params::dryseasonlmt**
minimum length of dry season for PFT to exist
- real, dimension(:), allocatable **ctem_params::bio2sap**
multiplying factor for converting biomass density to sapling density smaller numbers give faster colonization rates.
- real **ctem_params::bioclimrt**
mortality rate (1/year) for pfts that no longer exist within their pre-defined bioclimatic range
- real, dimension(:), allocatable **ctem_params::grescoef**
Growth respiration coefficient.
- real, dimension(:), allocatable **ctem_params::humicfac**
Humification factor - used for transferring carbon from litter into soil c pool.
- real, dimension(:), allocatable **ctem_params::laimin**
Minimum lai below which a pft doesn't expand.
- real, dimension(:), allocatable **ctem_params::laimax**
Maximum lai above which a pft always expands and lambdamax fraction of npp is used for expansion.
- real **ctem_params::lambdamax**
Max. fraction of npp that is allocated for reproduction/colonization.
- real **ctem_params::repro_fraction**
Fraction of NPP that is used to create reproductive tissues.
- real, dimension(2) **ctem_params::bmasthrs_fire**
min. and max. vegetation biomass thresholds to initiate fire, kgC/m²
- real **ctem_params::extnmois_veg**
extinction moisture content for estimating vegetation fire likeliness due to soil moisture
- real **ctem_params::extnmois_duff**
extinction moisture content for estimating duff layer fire likeliness due to soil moisture
- real **ctem_params::lwrlthrs**
lower cloud-to-ground lightning threshold for fire likelihood flashes/km².year
- real **ctem_params::hgrlthrs**
higher cloud-to-ground lightning threshold for fire likelihood flashes/km².year
- real **ctem_params::parmlght**
*parameter m (mean) and b of logistic distribution used for
**Parmlght was increased to 0.8 to make it so areas with higher amounts of lightning have higher lterm. The saturation is still the same, but the increase is more gradual at low lightning density. JM*
- real **ctem_params::parblght**
estimating fire likelihood due to lightning
- real **ctem_params::reparea**
typical area representing ctem's fire parameterization (km2)
- real **ctem_params::popdthrshld**
threshold of population density (people/km2) [Kloster et al., biogeosci. 2010]
- real **ctem_params::f0**
Fire spread rate in the absence of wind.
- real, dimension(:), allocatable **ctem_params::maxsprd**
- real, dimension(:), allocatable **ctem_params::max**
- real, dimension(:), allocatable **ctem_params::fire**
- real, dimension(:), allocatable **ctem_params::spread**

- real, dimension(:), allocatable **ctem_params::rate**
- real, dimension(:), allocatable **ctem_params::km**
- real, dimension(:), allocatable **ctem_params::hr**
- real, dimension(:), allocatable **ctem_params::frco2glf**
- real, dimension(:), allocatable **ctem_params::fraction**
- real, dimension(2), allocatable **ctem_params::of**
- real, dimension(:), allocatable **ctem_params::green**
- real, dimension(:), allocatable **ctem_params::leaf**
- real, dimension(:), allocatable **ctem_params::biomass**
- real, dimension(:), allocatable **ctem_params::converted**
- real, dimension(2), allocatable **ctem_params::to**
- real, dimension(:), allocatable **ctem_params::gases**
- real, dimension(:), allocatable **ctem_params::due**
- real, dimension(:), allocatable **ctem_params::combustion**
- real, dimension(:), allocatable **ctem_params::frco2blf**
- real, dimension(:), allocatable **ctem_params::brown**
- real, dimension(:), allocatable **ctem_params::frltrlf**
- real, dimension(:), allocatable **ctem_params::becoming**
- real, dimension(:), allocatable **ctem_params::litter**
- real, dimension(:), allocatable **ctem_params::after**
- real, dimension(:), allocatable **ctem_params::frltrlb**
- real, dimension(:), allocatable **ctem_params::frco2stm**
- real, dimension(:), allocatable **ctem_params::stem**
- real, dimension(:), allocatable **ctem_params::frltrstm**
- real, dimension(:), allocatable **ctem_params::frco2rt**
- real, dimension(:), allocatable **ctem_params::root**
- real, dimension(:), allocatable **ctem_params::frlrrt**
- real, dimension(:), allocatable **ctem_params::frlrrbn**
- real, dimension(:), allocatable **ctem_params::burned**

- real **ctem_params::finding**
- real, dimension(2), allocatable **ctem_params::temperature**
- real, dimension(2), allocatable **ctem_params::a**
parameter describing exponential soil carbon profile. used for estimating temperature of the carbon pool
- real **ctem_params::weighted**
- real **ctem_params::average**
- real **ctem_params::top**
- real **ctem_params::layer**
- real **ctem_params::bsratelt_g**
bare ground litter respiration rate at 15 c in kg c/kg c.year
- real **ctem_params::bsratesc_g**
bare ground soil c respiration rates at 15 c in kg c/kg c.year
- real, dimension(3) **ctem_params::combust**
how much deforested/chopped off biomass is combusted (these absolutely must add to 1.0!)
- real, dimension(3) **ctem_params::paper**

- how much deforested/chopped off biomass goes into short term storage such as paper*
- real, dimension(3) **ctem_params::furniture**
- how much deforested/chopped off biomass goes into long term storage such as furniture*
- real, dimension(2) **ctem_params::bmasthrs**
- biomass thresholds for determining if deforested area is a forest, a shrubland, or a bush kg c/m2*
- real, dimension(:), allocatable **ctem_params::bsrtstem**
- Base respiration rates for stem in kg c/kg c.year at 15 degrees celcius (values differ if using prescribed vs. competition run)*
- real, dimension(:), allocatable **ctem_params::bsrtroot**
- Base respiration rates for root in kg c/kg c.year at 15 degrees celcius (values differ if using prescribed vs. competition run)*
- real **ctem_params::minlvfr**
- Minimum live wood fraction.*
- real **ctem_params::rmlmoss25**
- Base dark respiration rate of moss umol CO2/m2/s.*
- real **ctem_params::tau25m**
- tau coefficient (rate at 25 Celcius) is computed on the basis of the specificity factor (102.33) times Kco2/Kh2o (28.38) to convert for value in solution to that based in air.*
- real **ctem_params::ektau**
- $\$J \text{ mol}^{-1} \$$!FLAG this is???*
- real **ctem_params::kc25**
- kinetic coef for CO2 at 25 C (Pa)*
- real **ctem_params::ko25**
- kinetic coef for O2 at 25C (rate) (Pa)*
- real **ctem_params::ec**
- Activation energy for Kc of CO2 ($\$J \text{ mol}^{-1} \$$) at 25C.*
- real **ctem_params::ej**
- Activation energy for electron transport, ($\$J \text{ mol}^{-1} \$$)*
- real **ctem_params::eo**
- Activation energy for Ko ($\$J \text{ mol}^{-1} \$$) at 25C.*
- real **ctem_params::evc**
- Activation energy for carboxylation ($\$J \text{ mol}^{-1} \$$) at 25C.*
- real **ctem_params::sj**
- Constant affecting J at low temperature ($\$J \text{ mol}^{-1} \$$) at 25C.*
- real **ctem_params::hj**
- Constant affecting J at high temperature ($\$J \text{ mol}^{-1} \$$) at 25C.*
- real **ctem_params::alpha_moss**
- Efficiency of conversion of incident photons into electrons(mol electron/mol photon),.*
- real **ctem_params::dctmin**
- minimum temperature of soil respiration,K (peatland soils)*
- real **ctem_params::dcbaset**
- base temperature for Q10, K (peatland soils)*
- real **ctem_params::bsrateltms**
- heterotrophic respiration base rate for peatlands (yr-1)*
- real **ctem_params::zlnmoss**
- natural logarithm of roughness length of moss surface.*
- real **ctem_params::thpmoss**
- pore volume of moss ($\$m^3/m^3 \$$)*
- real **ctem_params::thrmoss**
- Liquid water retention capacity of moss ($\$m^3/m^3 \$$)*
- real **ctem_params::thmmoss**

- residual liquid water content after freezing or evaporation of moss (m^3/m^3)*
- real **ctem_params::bmoss**
Clapp and Hornberger empirical "b" parameter of moss.
- real **ctem_params::psismoss**
Soil moisture suction at saturation of moss (m)
- real **ctem_params::grksmoss**
Saturated hydraulic conductivity of moss (m)
- real **ctem_params::hcpmoss**
Volumetric heat capacity of moss ($\text{J m}^{-3} \text{K}^{-1}$)
- real **ctem_params::grescoefmoss**
Moss growth respiration coefficient.
- real **ctem_params::rmortmoss**
Moss mortality rate constant (year⁻¹)
- real **ctem_params::humicfacmoss**
Humification ratio of moss litter.
- integer, dimension(:), allocatable **ctem_params::dayschk**
- integer, dimension(:), allocatable **ctem_params::number**
- integer, dimension(2), allocatable **ctem_params::days**

6.26.1 Detailed Description

This module holds CTEM globally accessible parameters. These parameters are used in all CTEM subroutines via use statements pointing to this module EXCEPT [PHTSYN3.f](#) which has the information passed in via arguments. This is a legacy thing.

The structure of this subroutine is variables that are common to competition/prescribe PFT fractions first, then the remaining variables are assigned different variables if competition is on, or not.

PFT parameters

Note the structure of vectors which clearly shows the CLASS PFTs (along rows) and CTEM sub-PFTs (along columns)

needle leaf	evg	dcd	—	—	—
broad leaf	evg	dcd-cld	dcd-dry	EVG-shrubs	DCD-shrubs
crops	c3	c4	—	—	—
grasses	c3	c4	sedges	—	—

We introduced three new PFTs for peatlands: evergreen shrubs, deciduous shrubs, and sedges. Evergreen shrubs, for example the ericaceous shrubs, are the common dominant vascular plants in bogs and poor fens while deciduous shrubs, such as the betulaceous shrubs, often dominate rich fens. Both shrubs are categorized as broadleaf trees in CLASS morphologically, but their phenological and physiological characteristics are more similar to those of needleleaf trees. The shrub tundra ecosystem is situated adjacent to needleleaf forest in the Northern Hemisphere (Kaplan et al., 2003) and they share similar responses to climate in ESMs (e.g. Bonan et al., 2002). Table~2 lists the key parameters for the peatland PFTs used in this model. (The photosynthesis and autotrophic respiration of vascular PFTs are modelled the same as in the original CTEM.)

6.27 src/ctem_statevars.f90 File Reference

this module contains the variable type structures:

Data Types

- type `ctem_statevars::ctem_switches`
switches for running the model, read from the joboptions file
- type `ctem_statevars::veg_rot`
CTEM's 'rot' vars.
- type `ctem_statevars::veg_gat`
CTEM's 'gat' vars.
- type `ctem_statevars::ctem_gridavg`
CTEM's grid average variables.
- type `ctem_statevars::ctem_tile_level`
CTEM's variables per tile.
- type `ctem_statevars::ctem_monthly`
CTEM's variables monthly averaged (per pft)
- type `ctem_statevars::ctem_gridavg_monthly`
CTEM's grid average monthly values.
- type `ctem_statevars::ctem_tileavg_monthly`
CTEM's variables per tile monthly values.
- type `ctem_statevars::ctem_annual`
CTEM's average annual values (per PFT)
- type `ctem_statevars::ctem_gridavg_annual`
CTEM's grid average annual values.
- type `ctem_statevars::ctem_tileavg_annual`
CTEM's variables per tile annual values.

Functions/Subroutines

- subroutine, public `ctem_statevars::alloc_ctem_vars` ()
- subroutine, public `ctem_statevars::initrowvars` ()

6.27.1 Detailed Description

this module contains the variable type structures:

1. c_switch - switches for running CTEM, read from the joboptions file
2. vrot - CTEM's 'rot' vars
3. vgat - CTEM's 'gat' vars
4. ctem_grd - CTEM's grid average variables
5. ctem_tile - CTEM's variables per tile
6. ctem_mo - CTEM's variables monthly averaged (per pft)
7. ctem_grd_mo - CTEM's grid average monthly values
8. ctem_tile_mo - CTEM's variables per tile monthly values
9. ctem_yr - CTEM's average annual values (per PFT)
10. ctem_grd_yr - CTEM's grid average annual values
11. ctem_tile_yr - CTEM's variables per tile annual values

6.31.1 Detailed Description

Canadian Terrestrial Ecosystem Model (CTEM)

6.32 src/CWCALC.f File Reference

Purpose: Check for freezing or thawing of liquid or frozen water on the vegetation canopy, and adjust canopy temperature and intercepted water stores accordingly.

Functions/Subroutines

- subroutine [cwcalc](#) (TCAN, RAICAN, SNOCAN, FRAIN, FSNOWC, CHCAP, HMFC, HTCC, FI, CMASS, ILG, IL1, IL2, JL)

6.32.1 Detailed Description

Purpose: Check for freezing or thawing of liquid or frozen water on the vegetation canopy, and adjust canopy temperature and intercepted water stores accordingly.

6.32.2 Function/Subroutine Documentation

6.32.2.1 subroutine [cwcalc](#) (real, dimension (ilg) *TCAN*, real, dimension(ilg) *RAICAN*, real, dimension(ilg) *SNOCAN*, real, dimension(ilg) *FRAIN*, real, dimension(ilg) *FSNOWC*, real, dimension (ilg) *CHCAP*, real, dimension (ilg) *HMFC*, real, dimension (ilg) *HTCC*, real, dimension (ilg) *FI*, real, dimension (ilg) *CMASS*, integer *ILG*, integer *IL1*, integer *IL2*, integer *JL*)

Parameters

<i>tcan</i>	Temperature of vegetation canopy [K] (T_c)
<i>raican</i>	Intercepted liquid water stored on the canopy [kgm^{-2}]
<i>snocan</i>	Intercepted frozen water stored on the canopy [kgm^{-2}]
<i>frainc</i>	Fractional coverage of canopy by liquid water []
<i>fsnowc</i>	Fractional coverage of canopy by frozen water []
<i>chcap</i>	Heat capacity of vegetation canopy [$Jm^{-2}K^{-1}$] (C_c)
<i>hmfc</i>	Energy associated with freezing or thawing of water in canopy interception stores [Wm^{-2}]
<i>htcc</i>	Internal energy change of canopy due to changes in temperature and/or mass [Wm^{-2}] (I_c)
<i>fi</i>	Fractional coverage of subarea in question on modelled area [] (X_i)
<i>cmass</i>	Mass of vegetation canopy [kgm^{-2}]

The change of internal energy I_c of the vegetation canopy as a result of the phase change processes treated here is calculated as the difference in I_c between the beginning and end of the subroutine:

$$\Delta I_c = X_i \Delta [C_c T_c] / \Delta t$$

where C_c represents the volumetric heat capacity of the canopy, T_c its temperature, Δt the length of the time step, and X_i the fractional coverage of the subarea under consideration relative to the modelled area.

If there is liquid water stored on the canopy and the canopy temperature is less than 0 C, the available energy sink HFREZ is calculated from CHCAP and the difference between TCAN and 0 C, and compared with HCONV, calculated as the energy sink required to freeze all of the liquid water on the canopy. If $HFREZ \leq HCONV$, the

amount of water that can be frozen is calculated using the latent heat of melting. The fractional coverages of frozen and liquid water FSNOWC and FRAIN C and their masses SNO CAN and RAICAN are adjusted accordingly, TCAN is set to 0 C, and the amount of energy involved is subtracted from the internal energy HTCC and added to HMFC. Otherwise all of the intercepted liquid water is converted to frozen water, and the energy available for cooling the canopy is calculated as HCOOL = HFREZ – HCONV. This available energy is applied to decreasing the temperature of the canopy, using the specific heat of the canopy elements, and the amount of energy that was involved in the phase change is subtracted from HTCC and added to HMFC.

If there is frozen water stored on the canopy and the canopy temperature is greater than 0 C, the available energy for melting, HMELT, is calculated from CHCAP and the difference between TCAN and 0 C, and compared with HCONV, calculated as the energy required to melt all of the frozen water on the canopy. If $HMELT \leq HCONV$, the amount of frozen water that can be melted is calculated using the latent heat of melting. The fractional coverages of frozen and liquid water FSNOWC and FRAIN C and their masses SNO CAN and RAICAN are adjusted accordingly, TCAN is set to 0 C, and the amount of energy involved is subtracted from HTCC and added to HMFC. Otherwise, all of the intercepted frozen water is converted to liquid water, and the energy available for warming the canopy is calculated as HWARM = HMELT – HCONV. This available energy is applied to increasing the temperature of the canopy, using the specific heats of the canopy elements, and the amount of energy that was involved in the phase change is subtracted from HTCC and added to HMFC.

In the final cleanup, the canopy heat capacity is recomputed and the remaining internal energy calculations are completed.

6.33 src/disturb.f90 File Reference

Update fractional coverages of pfts to take into account the area burnt by fire. Adjust all pools with new densities in their new areas and increase bare fraction.

Functions/Subroutines

- subroutine, public `disturbance_scheme::disturb` (stemmass, rootmass, gleafmas, bleafmas, thliq, THL \leftrightarrow W, THFC, uwind, vwind, lightng, fcancmx, litrmass, prbfrhuc, rmatctem, extnprob, transientPOPD, il1, il2, sort, nol2pfts, grclarea, thice, popdin, lucemcom, dofir, currlat, iday, fsnow, isand,
- subroutine, public `disturbance_scheme::burntobare` (il1, il2, nilg, sort, pvgbioms, pgavltms, pgavscms, fcancmx, burnveg, stemmass, rootmass, gleafmas, bleafmas, litrmass, soilcmas, pstemmass, pgleafmass, nppeg)

6.33.1 Detailed Description

Update fractional coverages of pfts to take into account the area burnt by fire. Adjust all pools with new densities in their new areas and increase bare fraction.

And while we are doing this also run a small check to make sure grid averaged quantities do not get messed up. Central module for all disturbance scheme-related operations

6.34 src/DRCOEF.f File Reference

Purpose: CALCULATES DRAG COEFFICIENTS AND RELATED VARIABLES FOR CLASS.

Functions/Subroutines

- subroutine `drcoef` (CDM, CDH, RIB, CFLUX, QG, QA, ZOMIN, ZOHIN, CRIB, TVIRTG, TVIRTA, VA, FI, ITER, ILG, IL1, IL2)

6.34.1 Detailed Description

Purpose: CALCULATES DRAG COEFFICIENTS AND RELATED VARIABLES FOR CLASS.

6.34.2 Function/Subroutine Documentation

6.34.2.1 subroutine drcoef (real, dimension (ilg) *CDM*, real, dimension (ilg) *CDH*, real, dimension (ilg) *RIB*, real, dimension (ilg) *CFLUX*, real, dimension (ilg) *QG*, real, dimension (ilg) *QA*, real, dimension (ilg) *ZOMIN*, real, dimension (ilg) *ZOHIN*, real, dimension (ilg) *CRIB*, real, dimension (ilg) *TVIRTG*, real, dimension (ilg) *TVIRTA*, real, dimension (ilg) *VA*, real, dimension (ilg) *FI*, integer, dimension(ilg) *ITER*, integer *ILG*, integer *IL1*, integer *IL2*)

Parameters

<i>cdm</i>	STABILITY-DEPENDENT DRAG COEFFICIENT FOR MOMENTUM.
<i>cdh</i>	STABILITY-DEPENDENT DRAG COEFFICIENT FOR HEAT.
<i>rib</i>	BULK RICHARDSON NUMBER.
<i>cflux</i>	$CD * MOD(V)$, BOUNDED BY FREE-CONVECTIVE LIMIT.
<i>zomin</i>	ROUGHNESS HEIGHTS FOR MOMENTUM/HEAT NORMALIZED BY REFERENCE HEIGHT.↵
<i>zohin</i>	ROUGHNESS HEIGHTS FOR MOMENTUM/HEAT NORMALIZED BY REFERENCE HEIGHT.↵
<i>crib</i>	$-RGAS*SLTHKEF/(VA**2)$, WHERE $SLTHKEF=-LOG(MAX(SGJ(ILEV),SHJ(ILEV)))$
<i>tvirtg</i>	"SURFACE" VIRTUAL TEMPERATURE.
<i>tvirta</i>	LOWEST LEVEL VIRTUAL TEMPERATURE.
<i>va</i>	AMPLITUDE OF LOWEST LEVEL WIND.
<i>fi</i>	FRACTION OF SURFACE TYPE BEING STUDIED.
<i>qg</i>	SATURATION SPECIFIC HUMIDITY AT GROUND TEMPERATURE.
<i>qa</i>	LOWEST LEVEL SPECIFIC HUMIDITY.
<i>iter</i>	INDEX ARRAY INDICATING IF POINT IS UNDERGOING FURTHER ITERATION OR NOT.

ZOM/ZOH: WORK ARRAYS USED FOR SCALING ZOMIN/ZOHIN ON STABLE SIDE, AS PART OF CALCULATION.↵

6.35 src/GATPREP.f File Reference

Purpose: Assign values to pointer vectors relating the location of elements on the "gathered" variable vectors to elements on the original two-dimensional arrays (latitude circle x mosaic tiles) for land grid cells.

Functions/Subroutines

- subroutine [gatprep](#) (ILMOS, JLMOS, IWMOS, JWMOS, NML, NMW, GCROW, FAREA, MOSID, NL, NM, ILG, IL1, IL2, IM)

6.35.1 Detailed Description

Purpose: Assign values to pointer vectors relating the location of elements on the "gathered" variable vectors to elements on the original two-dimensional arrays (latitude circle x mosaic tiles) for land grid cells.

6.35.2 Function/Subroutine Documentation

6.35.2.1 subroutine gatprep (integer, dimension (ilg) *ILMOS*, integer, dimension (ilg) *JLMOS*, integer, dimension (ilg) *IWMOS*, integer, dimension (ilg) *JWMOS*, integer *NML*, integer *NMW*, real, dimension (nl) *GCROW*, real, dimension (nl,nm) *FAREA*, integer, dimension (nl,nm) *MOSID*, integer *NL*, integer *NM*, integer *ILG*, integer *IL1*, integer *IL2*, integer *IM*)

Parameters

<i>nml</i>	Total number of mosaic tiles in land surface gather vectors
<i>nmw</i>	Total number of mosaic tiles in inland water gather vectors
<i>nl</i>	Hard-coded maximum number of grid cells
<i>nm</i>	Hard-coded maximum number of mosaic tiles
<i>ilg</i>	Hard-coded maximum number of elements in the gathered vectors
<i>im</i>	Maximum number of mosaic tiles within the grid cells in the array under consideration
<i>ilmos</i>	Index of grid cell corresponding to current element of gathered vector of land surface variables []
<i>jlmos</i>	Index of mosaic tile corresponding to current element of gathered vector of land surface variables []
<i>iwmos</i>	Index of grid cell corresponding to current element of gathered vector of inland water body variables []
<i>jwmos</i>	Index of mosaic tile corresponding to current element of gathered vector of inland water body variables []
<i>gcrow</i>	Real number identifier indicating whether the grid cell is land (-1.0), sea ice (+1.0), or ocean (0.0)
<i>farea</i>	Fractional coverage of mosaic tile on grid cell []
<i>mosid</i>	Mosaic tile type identifier (1 for land, 0 for inland water)

A looping operation is performed over the latitude circle, or array of grid cells, under consideration. If the grid cell is a land one (GCROW = -1.0), an additional internal loop is performed over all the mosaic tiles present. For each mosaic tile, if its fractional coverage is greater than zero, then if the mosaic type identifier MOSID is equal to 1 (indicating land), the counter of total mosaic tiles in the land surface gather vectors, NML, is incremented by one, and the elements of the vectors ILMOS and JLMOS corresponding to NML are set to the indices of the current grid cell and mosaic tile respectively. If MOSID is equal to zero (indicating inland water), the counter of total mosaic tiles in the inland water gather vectors, NMW, is incremented by one, and the elements of the vectors IWMOS and JWMOS corresponding to NMW are set to the indices of the current grid cell and mosaic tile respectively.

6.36 src/GRALB.f File Reference

Purpose: Calculate visible and near-IR ground albedos.

Functions/Subroutines

- subroutine [gralb](#) (ALVSG, ALIRG, ALVSGC, ALIRGC, ALGWV, ALGWN, ALGDV, ALGDN, THLIQ, FSNOW, ALVSU, ALIRU, FCMXU, AGVDAT, AGIDAT, FG, ISAND, ILG, IG, IL1, IL2, JL, IALG)

6.36.1 Detailed Description

Purpose: Calculate visible and near-IR ground albedos.

6.36.2 Function/Subroutine Documentation

- 6.36.2.1 subroutine `gralb` (real, dimension (ilg) *ALVSG*, real, dimension (ilg) *ALIRG*, real, dimension (ilg) *ALVSGC*, real, dimension (ilg) *ALIRGC*, real, dimension (ilg) *ALGWV*, real, dimension (ilg) *ALGWN*, real, dimension (ilg) *ALGDV*, real, dimension (ilg) *ALGDN*, real, dimension (ilg,ig) *THLIQ*, real, dimension (ilg) *FSNOW*, real, dimension (ilg) *ALVSU*, real, dimension (ilg) *ALIRU*, real, dimension (ilg) *FCMXU*, real, dimension (ilg) *AGVDAT*, real, dimension (ilg) *AGIDAT*, real, dimension (ilg) *FG*, integer, dimension (ilg,ig) *ISAND*, integer *ILG*, integer *IG*, integer *IL1*, integer *IL2*, integer *JL*, integer *IALG*)

Parameters

<i>alvsg</i>	Visible albedo of bare ground $\alpha_g(VIS)$
<i>alirg</i>	Near-IR albedo of bare ground $\alpha_g(NIR)$
<i>alvsge</i>	Visible albedo of ground under vegetation canopy []
<i>alirge</i>	Near-IR albedo of ground under vegetation canopy []
<i>algwv</i>	Visible albedo of wet soil for modelled area $\alpha_g(VIS, wet)$
<i>algwn</i>	Near-infrared albedo of wet soil for modelled area $\alpha_g(NIR, wet)$
<i>algdv</i>	Visible albedo of dry soil for modelled area $\alpha_g(VIS, dry)$
<i>algdn</i>	Near-infrared albedo of dry soil for modelled area $\alpha_g(NIR, dry)$
<i>thliq</i>	Volumetric liquid water content of soil layers $[m^3 m^{-3}]$
<i>alvsu</i>	Visible albedo of urban part of modelled area $\alpha_u(VIS)$
<i>aliru</i>	Near-IR albedo of urban part of modelled area $\alpha_u(NIR)$
<i>fcmxu</i>	Fractional coverage of urban part of modelled area $[X_u]$
<i>agvdat</i>	Assigned value of visible albedo of ground – optional []
<i>agidat</i>	Assigned value of near-IR albedo of ground – optional []
<i>fg</i>	Fractional coverage of bare soil on modelled area $[X_g]$
<i>fsnow</i>	Fractional coverage of snow on modelled area []
<i>isand</i>	Soil type flag based on sand content, assigned in subroutine CLASSB

If the ISAND flag for the surface soil layer is greater than or equal to zero (indicating mineral soil), first the urban area not covered by snow is evaluated. Next the visible and near-IR open ground albedos, $\alpha_g(VIS)$ and $\alpha_g(NIR)$, for each wavelength range, are calculated on the basis of the wet and dry ground albedos $\alpha_{g,wet}$ and $\alpha_{g,dry}$ which were assigned for the modelled area in CLASSB. Idso et al. (1975) found a correlation between the soil liquid moisture content in the top 10 cm of soil (represented in CLASS by that of the first soil layer, $\theta_{1,1}$) and the total surface albedo $\alpha_{g,T}$: for water contents less than $0.22 m^3 m^{-3}$, $\alpha_{g,T}$ took on the value of $\alpha_{g,dry}$; for liquid water contents greater than $0.26 m^3 m^{-3}$, $\alpha_{g,T}$ took on the value of $\alpha_{g,wet}$. For values of $\theta_{1,1}$ between these two limits, a linear relationship is assumed:

$$[\alpha_{g,T} - \alpha_{g,dry}] / [\theta_{1,1} - 0.22] = [\alpha_{g,wet} - \alpha_{g,dry}] / [0.26 - 0.22]$$

Thus, in GRALB for each of the two wavelength ranges α_g is calculated as follows:

$$\begin{aligned} \alpha_{g,T} &= \alpha_{g,dry} \quad \theta_{1,1} \leq 0.22 \\ \alpha_{g,T} &= \theta_{1,1} [\alpha_{g,wet} - \alpha_{g,dry}] / 0.04 - 5.50 [\alpha_{g,wet} - \alpha_{g,dry}] + \alpha_{g,dry} \quad 0.22 < \theta_{1,1} < 0.26 \\ \alpha_{g,T} &= \alpha_{g,wet} \quad 0.26 \leq \theta_{1,1} \end{aligned}$$

Afterwards, a correction is applied to $\alpha_g(VIS)$ and $\alpha_g(NIR)$ in order to account for the possible presence of urban surfaces over the modelled area. Visible and near-IR albedos are assigned for local urban areas, $\alpha_u(VIS)$ and $\alpha_u(NIR)$, as part of the background data (see the section on “Data Requirements”). A weighted average over the bare soil area X_g is calculated from the fractional snow-free urban area X_u as:

$$\begin{aligned} \alpha_{g,VIS} &= [X_u \alpha_{u,VIS} + (X_g - X_u) \alpha_{g,VIS}] / X_g \\ \alpha_{g,NIR} &= [X_u \alpha_{u,NIR} + (1.0 - X_u) \alpha_{g,NIR}] / X_g \end{aligned}$$

If the soil on the modelled area is not mineral, i.e. if the ISAND flag is less than zero, $\alpha_g(VIS)$ and $\alpha_g(NIR)$ are determined as follows:

If ISAND = -2, indicating organic soil, $\alpha_g(VIS)$ and $\alpha_g(NIR)$ are assigned values of 0.05 and 0.30 respectively from the lookup tables in the block data subroutine CLASSBD, corresponding to average measured values reported in Comer et al. (2000) [Comer2000-mz].

If ISAND = -3, indicating rock at the surface, $\alpha_g(VIS)$ and $\alpha_g(NIR)$ are assigned the dry ground values from CLASSB.

If ISAND = -4, indicating continental ice sheet or glacier, $\alpha_g(VIS)$ and $\alpha_g(NIR)$ are assigned values of 0.95 and 0.73 from CLASSBD, reflecting values reported for Antarctica (e.g. Sellers, 1974).

The above calculations are all performed if the flag IALG is set to zero. If IALG is set to one, indicating that assigned ground albedos are to be used instead of calculated values, $\alpha_g(VIS)$ and $\alpha_g(NIR)$ are set to the assigned values AGVDAT and AGIDAT respectively.

Lastly, the ground values of visible and near-IR albedo under the vegetation canopy are currently set equal to the open values (this approach is under review).

Parameters

<i>iveg</i>	Subarea type flag
<i>thliq</i>	Volumetric liquid water content of soil layer $[m^3m^{-3}](\theta_l)$
<i>thice</i>	Volumetric frozen water content of soil layer $[m^3m^{-3}](\theta_i)$
<i>tbarw</i>	Temperature of water in soil layer [C]
<i>fdt</i>	Water flow at soil layer interfaces during current time step [m]
<i>tfd</i>	Temperature of water flowing between soil layers [C]
<i>basflw</i>	Base flow from bottom of soil column [m]
<i>tbasfl</i>	Temperature of base flow from bottom of soil column [K]
<i>runoff</i>	Total runoff from soil column [m]
<i>trunof</i>	Temperature of total runoff from soil column [K]
<i>qfg</i>	Evaporation from soil surface (diagnostic) $[kgm^{-2}s^{-1}]$
<i>wlost</i>	Residual amount of water that cannot be supplied by surface stores $[kgm^{-2}]$
<i>fi</i>	Fractional coverage of subarea in question on modelled area [] (X_i)
<i>evap</i>	Evaporation rate from ground surface $[ms^{-1}]$
<i>r</i>	Rainfall rate at ground surface $[ms^{-1}]$
<i>zpond</i>	Depth of ponded water on soil surface [m]
<i>dt</i>	Time period over which water movement takes place [s]

<i>igrn</i>	Flag to indicate whether calculations in subroutine GRINFL are done
<i>lzf</i>	Index of soil layer in which wetting front is located
<i>igrd</i>	Flag to indicate whether calculations in this subroutine are to be done
<i>igdr</i>	Index of soil layer in which bedrock is encountered
<i>thpor</i>	Pore volume in soil layer $[m^3m^{-3}](\theta_p)$
<i>thlret</i>	Liquid water retention capacity for organic soil $[m^3m^{-3}](\theta_{l,ret})$
<i>thlmin</i>	Residual soil liquid water content remaining after freezing or evaporation $[m^3m^{-3}](\theta_{l,min})$
<i>bi</i>	Clapp and Hornberger empirical "b" parameter [] (b)
<i>psisat</i>	Soil moisture suction at saturation $[m](\Psi_{sat})$
<i>grksat</i>	Hydraulic conductivity of soil at saturation $[ms^{-1}](K_{sat})$
<i>thfc</i>	Field capacity $[m^3m^{-3}]$
<i>delzw</i>	Permeable depth of soil layer $[m](\Delta_{zg,w})$
<i>xdrain</i>	Drainage index for water flow at bottom of soil profile []
<i>isand</i>	Sand content flag

In loop 50, the flag IGRD is first set to 1 for all grid cells where the calculations in this subroutine are to be performed. The necessary conditions are: that the surface being modelled is not a glacier or ice sheet (ISAND > -4); that the time period DT is greater than zero; that the infiltration calculations in subroutine GRINFL are not simultaneously being performed (IGRN = 0); and that the rainfall rate and the depth of ponded water are both vanishingly small. If any of these conditions is not met, IGRD is set to zero.

In loop 100, if the surface being modelled is not an ice sheet (ISAND = -4) and if the soil layer in question is not completely rock (ISAND = -3), the maximum possible water content of each soil layer, THLMAX, is calculated as the maximum of the available pore volume THPOR – THICE (where THPOR is the total pore volume and THICE is the ice content of the layer), the actual liquid water content THLIQ, and the minimum residual liquid water content THLMIN. The last two conditions are required because in the case of a saturated soil undergoing freezing, since water expands when frozen, the sum of the liquid and frozen volumetric water contents may be greater than the pore volume, and thus THLIQ or THLMIN may be greater than THPOR – THICE. An effective saturated hydraulic conductivity GRKSATF of the soil layer is also defined, applying an empirical correction for the presence of ice. This ice content factor, fice, is calculated from Zhao and Gray (1997) as:

$$f_{ice} = [1.0 \sim \min((\theta_p - \theta_{l,min})/\theta_p, \theta_i/\theta_p)]^2$$

The pore volume of the soil layer is corrected for the presence of ice by defining the effective porevolume THPORF as equivalent to THLMAX.

In loops 150 and 200, the theoretical amounts of water FDT flowing across the soil layer boundaries are calculated. FDT is evaluated as the product of the flow rate F(z) at the given depth z, and the period of time (DT) over which the flow is occurring. At z=0, the water flux is simply equal to the soil surface evaporation rate. Within the soil, the flow rate F at a given depth z is obtained using equation 21 from Verseghe (1991):

$$F(z) = K(z)[-b\Psi(z)/\theta_l(z) \bullet d\theta_l/dz + 1]$$

where K(z) is the hydraulic conductivity and psi(z) is the soil moisture suction at depth z, and b is an empirical parameter developed by Clapp and Hornberger (1978) [Clapp1978-898]. K(z) and $\Psi(z)$ are calculated following Clapp and Hornberger as

$$K(z) = K_{sat}(\theta_l/\theta_p)^{(2b+3)} \quad \Psi(z) = \Psi_{sat}(\theta_l/\theta_p)^{(-b)}$$

where K_{sat} and Ψ_{sat} are the values of K and Ψ respectively at saturation.

At the bottom of the permeable soil depth, in layer IGDR, if the liquid water content of the soil is greater than the field capacity, the vertical flow out of the bottom of the soil profile is calculated using a relation derived from Soulis et al. (2010):

Between soil layers, values of K(z) and $\Psi(z)$ must be determined. This requires the estimation of soil properties at the layer interfaces. For θ_l , θ_p and $d(\theta_l)/dz$, slightly different approaches are followed if the permeable soil layer thickness DELZW increases with depth (the normal case), or if it decreases between one soil layer and the next (indicating the presence of an impermeable barrier at some depth in the second layer). In the first case, the pore volume THPBND, liquid water content THLBND, and liquid water gradient DTHLDZ are simply calculated as arithmetic averages of the values above and below the interface. This has the effect of weighting the interface values towards the upper layer values, roughly emulating a surfaceward exponential decay curve of liquid water content. In the second case, in order to avoid a spurious weighting towards the lower layer, the gradients of liquid water content and pore volume between the upper and lower layers are calculated as linear relations, and then solved for

the values at the interface.

The Clapp and Hornberger b parameter at the interface is calculated as a simple average of the values in the upper and lower soil layers. The saturated hydraulic conductivity $K_{sat,bnd}$ is calculated as a harmonic mean, and the saturated soil moisture suction $\Psi_{sat,bnd}$ as a geometric mean, of the top and bottom layer values:

$$K_{sat,bnd} = K_{sat,t} K_{sat,b} (\Delta z_{g,w,t} + \Delta z_{g,w,b}) / (K_{sat,t} \Delta z_{g,w,b} + K_{sat,b} \Delta z_{g,w,t})$$

$$\Psi_{sat,bnd} = \Psi_{sat,t}^{\Delta z_{g,w,t} / (\Delta z_{g,w,t} + \Delta z_{g,w,b})} \Psi_{sat,b}^{\Delta z_{g,w,b} / (\Delta z_{g,w,t} + \Delta z_{g,w,b})}$$

Finally, $K(z)$, $\Psi(z)$ and $F(z)$ at the interface are calculated from the equations given above. At the end of the loop, if set to zero behind the soil layer LZF containing the wetting front, and the flow rate at the bottom of LZF is constrained to be ≥ 0 .

In the next several loops, checks are carried out to ascertain whether the theoretically determined flow rates at the soil layer interfaces can be supported by the water contents in the layers. At the beginning of loop 250, the soil surface evaporation rate is addressed. A trial liquid water content THTEST is calculated for the first soil layer, reflecting the removal of the evaporated water. If THTEST is less than the minimum soil water content, $F(0)$ is set to zero and θ_l is set to $\theta_{l,min}$. The excess surface flux that was not met by the removed liquid water is converted to a frozen water content, and an attempt is made to remove it from the frozen water in the layer. (The energy involved in converting the required frozen water mass to liquid water is obtained by decreasing the water temperature of the layer.) The frozen water content of the layer is adjusted to reflect the removal of the required amount. If the demand exceeds the supply of frozen water available, the frozen water content is set to zero, the diagnostic evaporative flux QFG at the soil surface is adjusted, and the remaining water flux not able to be met by the first soil layer is assigned to the variable WLOST.

In the remainder of the 250 loop, checks are carried out for soil layers with liquid water contents already effectively equal to $\theta_{l,min}$. If the flux at the top of the layer is upward and that at the bottom of the layer is downward, both are set to zero. If both are downward, only the flux at the bottom is set to zero; if both are upward, only the flux at the top is set to zero. If the soil layer is an organic one and the liquid water content is less than the layer retention capacity THLRET and the flux at the bottom of the layer is downward, it is set to zero.

In the 300 loop, checks are carried out for soil layers with liquid water contents already effectively equal to THLMAX. If the flux at the top of the layer is downward and that at the bottom of the layer is upward, both are set to zero. If both are downward, then if the top flux is greater than the bottom flux, it is set equal to the bottom flux. If both are upward, then if magnitude of the bottom flux is greater than that of the top flux, it is set equal to the top flux.

In the 400 loop, for each soil layer THTEST is recalculated as the liquid water content resulting from the updated boundary fluxes, and is compared with a residual value THLTHR. For organic soil layers deeper than the first layer, THLTHR is set to the minimum of $\theta_{l,ret}$ and θ_l , since only evapotranspiration can cause the soil moisture to fall below the retention capacity. (The first layer is excepted because surface evaporation can drive its moisture content below $\theta_{l,ret}$.) For mineral soils, $\theta_{l,min}$ is set to THLMIN. If $THTEST < THLTHR$, then if the flow at the bottom of the soil layer is downward, it is recalculated as the sum of the flow at the top of the layer plus the amount of water that must be removed to make the liquid water content of the layer equal to THLTHR. If the flow at the bottom of the layer is upward, the flow at the top of the layer is recalculated as the sum of the flow at the bottom of the layer minus the amount of water that must be removed to make the liquid water content of the layer equal to THLTHR. THTEST of the current layer is then reset to THLTHR, and THTEST of the overlying and underlying layers (if any) are recalculated using the new interface fluxes.

In the 500 loop, for each soil layer THTEST is compared with THLMAX. If $THTEST > THLMAX$, two temporary variables are defined: WLIMIT as the amount of water required to raise the liquid water content of the soil layer to THLMAX, and WEXCES as the amount of water representing the excess of THTEST over THLMAX. If the flux at the top of the layer is downward and the flux at the bottom of the layer is upward, then if the negative of the flux at the bottom of the layer is greater than WLIMIT, it is set equal to -WLIMIT and the flux at the top is set to zero; otherwise WEXCES is subtracted from the flux at the top. If both the flux at the top and the flux at the bottom are downward, then WEXCES is subtracted from the flux at the top. If both are upward, then WEXCES is added to the flux at the bottom, and a correction is applied to the flux at the bottom of the underlying layer. Finally, THTEST is recalculated for all the soil layers using the new interface fluxes.

In the first part of the 600 loop, a correction is performed in the unlikely event that as a result of the above adjustments, the flux at the bottom of the last permeable soil layer has become upward. If this occurs, all of the fluxes above are corrected by the inverse of this same amount. However, this will result in a small spurious upward water flux at the surface. Since the liquid water flows are now accounted for, an attempt is made, as in loop 250, to remove

the required water from the frozen water store in the first layer. The excess that cannot be supplied from this source is assigned to WLOST.

In the second part of the 600 loop, the temperatures TFDT of the water fluxes at the top and bottom of the layers in the permeable soil profile are set equal to the temperatures of the water in the first and last layers respectively. The flow at the bottom of the profile and the temperature of the flow are used to update BASFLW and TBASFL, the baseflow from the current subarea and its temperature, and RUNOFF and TRUNOF, the total runoff from the grid cell in question and its temperature.

In the 700 loop, for each successive soil layer the temperature of the water flux at the bottom of the layer is first assigned. If the flux is downward, TFDT is set to the temperature of the water in the current layer; if it is upward, TFDT is set to the temperature of the water in the layer below. The temperature of the water in the current layer is then updated using the FDT and TFDT values at the top and bottom of the layer, and the liquid water content of the layer is set to THTEST.

Parameters

<i>iveg</i>	Subarea type flag
<i>thliq</i>	Volumetric liquid water content of soil layer $[m^3m^{-3}](\theta_l)$
<i>thice</i>	Volumetric frozen water content of soil layer $[m^3m^{-3}](\theta_i)$
<i>tbarw</i>	Temperature of water in soil layer [C]
<i>basflw</i>	Base flow from bottom of soil column [m]
<i>tbasfl</i>	Temperature of base flow from bottom of soil column [K]
<i>runoff</i>	Total runoff from soil column [m]
<i>trunof</i>	Temperature of total runoff from soil column [K]
<i>qfg</i>	Evaporation from soil surface (diagnostic) $[kgm^{-2}s^{-1}]$
<i>wlost</i>	Residual amount of water that cannot be supplied by surface stores $[kgm^{-2}]$
<i>zfav</i>	Average depth of wetting front over current time step [m]
<i>thlinv</i>	Liquid water content behind the wetting front $[m^3m^{-3}]$
<i>lzfav</i>	Soil layer index in which the average position of the wetting front occurs
<i>fi</i>	Fractional coverage of subarea in question on modelled area []
<i>evap</i>	Evaporation rate from ground surface $[ms^{-1}]$
<i>r</i>	Rainfall rate at ground surface $[ms^{-1}]$
<i>tr</i>	Temperature of rainfall [C]
<i>tpond</i>	Temperature of ponded water [C]
<i>zpond</i>	Depth of ponded water on soil surface [m]
<i>dt</i>	Time period over which water movement takes place [s]
<i>thpor</i>	Pore volume in soil layer $[m^3m^{-3}](\theta_p)$
<i>thlret</i>	Liquid water retention capacity for organic soil $[m^3m^{-3}](\theta_{l,ret})$
<i>thlmin</i>	Residual soil liquid water content remaining after freezing or evaporation $[m^3m^{-3}](\theta_{l,min})$
<i>bi</i>	Clapp and Hornberger empirical "b" parameter [] (b)
<i>psisat</i>	Soil moisture suction at saturation $[m](\Psi_{sat})$
<i>grksat</i>	Hydraulic conductivity of soil at saturation $[ms^{-1}](K_{sat})$
<i>thlrat</i>	Fractional saturation of soil behind the wetting front [] (f_{inf})
<i>thfc</i>	Field capacity $[m^3m^{-3}]$
<i>delzw</i>	Permeable depth of soil layer $[m](\Delta z_{g,w})$
<i>zbotw</i>	Depth to permeable bottom of soil layer [m]
<i>xdrain</i>	Drainage index for water flow at bottom of soil profile []
<i>delz</i>	Overall thickness of soil layer [m]
<i>isand</i>	Sand content flag
<i>igrn</i>	Flag to indicate whether calculations in this subroutine are to be done
<i>igrd</i>	Flag to indicate whether calculations in subroutine GRDRAN are to be done
<i>igdr</i>	Index of soil layer in which bedrock is encountered

In loop 50, the flag IGRN is first set to 1 for all grid cells where the calculations in this subroutine are to be performed. The necessary conditions are: that the surface being modelled is not a glacier or ice sheet (ISAND > -4); that the time period DT is greater than zero; and that either the rainfall rate is greater than zero or that ponded water exists on the surface. If any of these conditions is not met, IGRN is set to zero.

In loop 100, a series of local arrays THLIQX, THICEX, TBARWX, DELZX and ZBOTX are defined for use in the subsequent infiltration calculations, with a "y" dimension of IG+1, where IG is the number of soil layers. The entries from 1 to IG are set equal to the corresponding values in THLIQ, THICE, TBARW, DELZW and ZBOTW. An effective saturated hydraulic conductivity GRKSATF is calculated for each soil layer, applying an empirical correction for the presence of ice. This ice content factor, f_{ice} , is calculated from Zhao and Gray (1997) as:

$$f_{ice} = [1.0 \sim \min(1.0, \theta_i/\theta_p)]^2$$

To further account for the presence of ice, a modified pore volume THPORF for the soil layer is calculated as the maximum of the available pore volume $\theta_p - \theta_i$ (where θ_p is the total pore volume and θ_i is the ice content of the layer), the actual liquid water content θ_l , and the minimum residual liquid water content $\theta_{l,min}$. (The last two conditions are required because in the case of a saturated soil undergoing freezing, since water expands when frozen, the sum of the liquid and frozen volumetric water contents may be greater than the pore volume, and thus θ_l or $\theta_{l,min}$ may be greater than $\theta_p - \theta_i$.) Finally, the water content THLINF and the hydraulic conductivity $G \leftrightarrow RKINF$ behind the wetting front are evaluated, following the analysis of Green and Ampt (1911) [Green1911-gy]

and treating the change in soil moisture due to infiltration as a downward-propagating square wave. THLINF is calculated as the maximum of $f_{inf}(\theta_p \sim \theta_i)$, θ_l , and $\theta_{l,min}$, where f_{inf} represents the fractional saturation of the soil behind the wetting front, corresponding to a hydraulic conductivity of half the saturated value (this correction is applied in order to account for the fact that as infiltration occurs, a small amount of air is usually trapped in the soil). GRKINF is calculated from GRKSATF, THLINF and THPORF, using the classic Clapp and Hornberger (1978) [Clapp1978-898] equation

$$K(z) = K_{sat}(\theta_l/\theta_p)^{(2b+3)}$$

where $K(z)$ is the hydraulic conductivity at a depth z , K_{sat} is the hydraulic conductivity at saturation, θ_p is the pore volume and b is an empirical coefficient.

In loop 150, values for the IG+1 entries in each of the above arrays are assigned. If the permeable thickness DELZW of the IG layer is less than its overall thickness DELZ (indicating the presence of bedrock) the IG+1 entries are set to 0; otherwise they are set to the values for the IG layer in the case of THLIQX, THICEX, TBARWX and THLINF, and for DELZX and ZBOTX they are set to large positive numbers. GRKINF is set to the value for the IG layer multiplied by the drainage parameter XDRAIN, which takes a value of 0 if the soil is underlain by an impermeable layer (as in a bog), and a value of 1 otherwise.

In loop 200, the soil water suction across the wetting front ψ_f is calculated for each soil layer, using equation 25 in Versegly (1991):

$$\Psi_f = b[\Psi_{inf}K_{inf} - \Psi(z)K(z)]/[K_{inf}(b+3)]$$

where Ψ_{inf} and K_{inf} are the soil moisture suction and the hydraulic conductivity behind the wetting front, and $\Psi(z)$ and $K(z)$ are the soil moisture suction and the hydraulic conductivity ahead of the wetting front. The soil moisture suction values are obtained using the classic Clapp and Hornberger (1978) equation:

$$\Psi(z) = \Psi_{sat}(\theta_l/\theta_p)^{(-b)}$$

where Ψ_{sat} is the soil moisture suction at saturation.

In loop 400, a test is carried out to determine whether saturated conditions are already present in the soil. Generally it is assumed that a period of unsaturated flow occurs initially, so the flag IFILL is set to 1, the depth of the wetting front ZF is set to zero, and the flag LZF indicating the index of the soil layer in which the wetting front occurs is set to 1. If a pond is present on the soil surface or if the hydraulic conductivity of the first soil layer is very small, it is deemed that saturated flow begins immediately, so IFILL is set to zero. Then each soil layer is checked in turn, to ascertain whether the liquid water content is greater than THLINF. If so, it is concluded that saturated flow is occurring in this layer; ZF is set to ZBOTW, the depth of the bottom of the soil layer, LZF is set to the index of the next layer, and IFILL is set to zero. For each layer found to be undergoing saturated flow, its water content is stored in the J+1 level of the water movement matrix WMOVE, and its water temperature is stored in the J+1 level of the matrix TMOVE. The counter NINF is set to the number of soil layers behind and including the one with the wetting front, plus 2.

A series of subroutines is called to complete the infiltration calculations. Subroutine WFILL treats the period of unsaturated flow up to the point when saturated flow begins. Subroutine WFLOW treats the period of saturated flow. Subroutine WEND reassigns liquid water contents and temperatures at the conclusion of the infiltration period. T \leftrightarrow HLIQ, THICE and TBARW are then set to the corresponding updated values of THLIQX, THICEX and TBARWX. The average depth of the wetting front in the soil layer in which it occurs, the index of the soil layer, and the moisture content behind the wetting front are stored in output variables ZFAV, LZFAV and THLINV respectively. Finally, if there is any time remaining in the current time step following the infiltration period, subroutine GRDRAN is called to treat the movement of soil water over the remainder of the time step.

Parameters

<i>tbar</i>	Temperature of ice layer $[C](T_{av}(\Delta z))$
<i>hmfg</i>	Energy associated with freezing or thawing of water in ice layer $[Wm^{-2}]$
<i>htc</i>	Internal energy change of ice layer due to conduction and/or change in mass $[Wm^{-2}](I)$
<i>gflux</i>	Heat flow between ice layers $[Wm^{-2}](G(\Delta z))$
<i>tpond</i>	Temperature of ponded water $[C]$
<i>zpond</i>	Depth of ponded water $[m]$
<i>tsnow</i>	Temperature of the snow pack $[C]$

<i>rhosno</i>	Density of snow pack [kgm^{-3}]
<i>zsnow</i>	Depth of snow pack [m]
<i>hcpsno</i>	Heat capacity of snow pack [$Jm^{-3}K^{-1}$]
<i>albsno</i>	Albedo of snow []
<i>htcs</i>	Internal energy change of ice layer due to conduction and/or change in mass [Wm^{-2}](I_j)
<i>wtrs</i>	Water transferred into or out of the snow pack [$kgm^{-2}s^{-1}$]
<i>wtrg</i>	Water transferred into or out of the ice [$kgm^{-2}s^{-1}$]
<i>runoff</i>	Total runoff from ice column [m]
<i>trunof</i>	Temperature of total runoff from ice column [K]
<i>ovrflw</i>	Overland flow from top of ice column [m]
<i>tovrfl</i>	Temperature of overland flow from top of ice column [K]
<i>fi</i>	Fractional coverage of subarea in question on modelled area $\square(X)$
<i>evap</i>	Evaporation rate from ice surface [ms^{-1}]
<i>r</i>	Rainfall rate at ice surface [ms^{-1}]
<i>tr</i>	Temperature of rainfall [C]
<i>gzero</i>	Heat flow into ice surface [Wm^{-2}]($G(0)$)
<i>g12</i>	Heat flow between first and second ice layers [Wm^{-2}]($G(\Delta z1)$)
<i>g23</i>	Heat flow between second and third ice layers [Wm^{-2}]($G(\Delta z2)$)
<i>qmelt</i>	Energy available for melting of ice [Wm^{-2}]
<i>wsnow</i>	Liquid water content of snow pack [kgm^{-2}]
<i>zplim</i>	Limiting depth of ponded water [m]
<i>ggeo</i>	Geothermal heat flux at bottom of modelled ice profile [Wm^{-2}]
<i>hcp</i>	Heat capacity of ice layer [$Jm^{-3}K^{-1}$]
<i>isand</i>	Sand content flag
<i>delz</i>	Overall thickness of ice layer [m](Δz)

In the 100 loop, any rainfall or snowmelt R reaching the ice surface is added to the ponded water on the surface. The ponded water temperature is calculated as the weighted average of the existing pond and the rainfall or snowmelt added, and the change in internal energy HTC of the first ice layer is updated using the temperature of the added water.

If a full-scale hydrological modelling application is not being run, that is, if only vertical fluxes of energy and moisture are being modelled, the flag IWF will have been pre-set to zero. In this case, overland flow of water is treated using a simple approach: if the ponded depth of water on the soil surface ZPOND exceeds a pre-determined limiting value ZPLIM, the excess is assigned to overland flow. The total runoff from the ice sheet, RUNOFF, is incremented by the excess of the ponded water, and the overland flow for the whole grid cell OVRFLW is incremented by the product of the excess ponded water and the fractional area of the grid cell. The temperature of the overall runoff from the modelled area TRUNOF, and the temperature of the overland flow for the grid cell TOVRFL, are calculated as weighted averages over their previous values and the ponded water temperature TPOND. The internal energy change HTC of the first soil layer is adjusted for the amount of water lost, and ZPOND is set to ZPLIM.

If the temperature of the remaining ponded water is greater than 0 C, the sink of energy required to cool it to 0 C, HCOOL, is calculated and compared with the amount of energy required to warm the first ice layer to 0 C, HWARM. If HWARM > HCOOL, the energy sink of the first layer is used to cool the ponded water to 0 C, and the layer temperature is updated accordingly. Otherwise, the ponded water temperature and the temperature of the first ice layer are both set to 0 C, and the excess energy source given by HCOOL-HWARM is added to the heat available for melting ice, QMELT.

In loop 125, if the temperature of the first ice layer is less than -2 C after the above operations (i.e. if it is not very close to 0 C), and if the ponded water depth is not vanishingly small, freezing of the ponded water can take place. The energy sink required to freeze all of the ponded water, HFREZ, is calculated and compared with HWARM, the amount of energy required to raise the temperature of the first ice layer to 0 C. If HWARM > HFREZ, then HFREZ is converted into an equivalent temperature change using the heat capacity of ice, and added to the temperature of the first ice layer. HFREZ is also used to update HMFG, the diagnosed energy used for phase changes of water in the first ice layer. The internal energy of the first soil layer, HTC, is adjusted to account for the loss of the ponded water, which is assumed to be added to the snow pack. The ponded water is converted into a frozen depth ZFREZ, which is used to update the internal energy of the snow pack, HTCS. If there is not a pre-existing snow pack, the snow albedo is set to the limiting low value of 0.50. The temperature and density of the snow pack are recalculated as weighted averages over the original values and the frozen amount that has been added. ZFREZ is added to the snow depth ZSNOW. The snow heat capacity is recalculated using the new value of the snow density. Finally,

the diagnostic amounts of water transferred to the snow pack, WTRS, and from the ice, WTRG, are updated using ZFREZ.

In the 150 loop the heat fluxes between the ice layers are calculated for the optional multiple-layer configuration, in which the standard third layer, normally with a thickness of 3.75 m, can be subdivided into smaller layers and extended to a greater depth if desired. (The heat fluxes at the ice surface, and between the first and second and the second and third layers, were already calculated in the CLASST subroutines.) The remaining fluxes are calculated by using a simple linearization of the soil temperature profile. The expression for the ground heat flux at a depth z , $G(z)$, which depends on the thermal conductivity $\lambda(z)$ and the temperature gradient, is written as:

$$G(z) = \lambda(z) dT(z)/dz$$

The linearized form is thus:

$$G_j = 2\lambda_i(T_{j-1} \sim T_j)/(\Delta z_{j-1} + \Delta z_j)$$

where G_j is the heat flux at the top of layer j , T_j and Δz_j refer to the temperature and thickness of the layer, and λ_i is the thermal conductivity of ice.

In the 200 loop a value is assigned to the temperature at the bottom of the ice profile, TBOT, and the temperatures for the first three ice layers are stepped ahead. If the standard three-layer configuration is being used, TBO ← T is obtained by making use of the assumption (see documentation for subroutine TNPREP) that the variation of temperature T with depth z within each soil layer can be modelled using a quadratic equation:

$$T(z) = 1/2az^2 + bz + c$$

It can be shown that the temperature at the bottom of a given soil layer, $T(\Delta z)$, is related to the temperature at the top of the layer $T(0)$ and the heat fluxes at the top and bottom of the layer, $G(0)$ and $G(\Delta z)$, as follows:

$$T(\Delta z) = T(0) - (\Delta z/2\lambda_i)[G(0) + G(\Delta z)]$$

Making use of the continuity requirement that the heat flux and temperature at the bottom of a given layer must be equal to the heat flux and temperature at the top of the layer beneath it, an expression for the temperature at the bottom of the third ice layer can be obtained as a function of the temperature at the surface and the fluxes between the ice layers:

$$T(\Delta z_3) = T(0) \sim G(\Delta z_2)[\Delta z_3 + \Delta z_2] + G(\Delta z_1)[\Delta z_2 + \Delta z_1] + G(0)\Delta z_{21}/2\lambda_i$$

The surface temperature $T(0)$ is obtained by integrating the equation for $T(z)$ to obtain an expression for the average layer temperature $T_{av}(\Delta z)$, and then inverting this to solve for $T(0)$:

$$T(0) = T_{av}(\Delta z_1) + (\Delta z_1/3\lambda_i)[G(0) + 1/2G(\Delta z_1)]$$

The third layer temperature is then updated using the geothermal flux GGEO. If the optional multiple-layer configuration is used, TBOT is simply set to the temperature of the lowest layer. In either the standard or the multiple-layer case, the first three layer temperatures are updated using the heat fluxes at the surface, between the first and second layers and between the second and third layers, which were determined in the CLASST subroutines. Finally, the latter fluxes are assigned to the appropriate levels in the diagnostic GFLUX vector.

In the 250 loop, the GFLUX values determined in the 150 loop are used to update the temperatures in the third and lower ice layers for the multiple-layer configuration. The calculations are bracketed by a determination of the change of internal energy I_j of the ice layers as a result of the heat fluxes, obtained as the difference in I_j between the beginning and end of the calculations:

$$\Delta I_j = X_i \Delta [C_i \Delta z_j T_{av}(\Delta z_j)]/\Delta t$$

where C_i is the heat capacity of ice, Δt is the length of the time step, and X_i is the fractional coverage of the subarea under consideration relative to the modelled area.

In the 300 loop, checks are carried out to determine whether any of the ice layer temperatures has overshot 0 C as a result of the calculations in the previous loop. If so, the excess energy is assigned to a temporary variable QADD and is also added to the total heat available for melting of the ice, QMELT. QADD is subtracted from the internal energy of the layer in questions and is added to the internal energy of the first layer, since melting is assumed to proceed from the top downwards. The temperature of the layer is reset to 0 C. Finally, the first half of a calculation of the change of internal energy of each ice layer is performed, to be completed at the end of the subroutine.

In the next three loops, the ice layers are adjusted downward to account for the removal of mass at the surface by melting or sublimation. First, the temperature TMOVE of the ice into which the layer is moving is set to the

temperature of the layer below it. TMOVE for the bottom layer is set to TBOT. A depth of ice ZMELT is calculated as the amount of ice for which QMELT is sufficient to both raise its temperature to 0 C (if necessary) and melt it. The temperature of the overall runoff and the overland flow are updated as averages of the original temperature and the meltwater temperature (assumed to be at the freezing point), weighted according to their respective amounts, and the overall runoff and overland flow are incremented by ZMELT (with ZMELT converted to an equivalent water depth). The energy used for the melting of ice is calculated from ZMELT and added to HMFG for the first layer, and the amount of energy used to raise the layer temperature to 0 C is added to HTC for the first layer. The total depth of downward adjustment of the ice layers, ZMOVE, is obtained as the sum of ZMELT and the sublimation depth, calculated from EVAP. This amount is added to the diagnostic variable WTRG. Finally, the new temperature of each ice layer is calculated over the layer thickness DELZ as the average of the original temperature weighted by DELZ-ZMOVE and TMOVE weighted by ZMOVE.

In the next loops, the ice layers are adjusted upward to account for addition of mass at the surface by conversion of snow to ice. Snow is converted to ice if the depth of the snow pack exceeds 10 m, or if the density exceeds 900kgm^{-3} (approaching that of ice). In the first case the excess over and above 10 m is converted; in the second, the whole snow pack is converted. These calculations are performed in the 500 loop, bracketed by a calculation of the change in internal energy of the snow pack, HTCS. In both cases the first level of the ice level movement matrix WMOVE is set to the amount of snow that is converted, expressed as a depth of ice, and the first level of the temperature matrix TMOVE is set to the snow temperature. The amount of converted snow is added to the diagnostic variables WTRS and WTRG. The depth, density and heat capacity of the snow are recalculated. If the entire snow pack is being converted and the water content WSNOW was non-zero, WSNOW is subtracted from WTRS and added to WTRG, and is also added to the total runoff and the overland flow. The runoff and overland flow temperatures are updated accordingly. The snow temperature and water content are reset to zero. The amount of ice that is lost to the bottom of the profile is added to the total runoff, and the runoff temperature is updated accordingly.

In the remaining parts of the code, the actual adjustment of ice layer positions is performed. First the levels of the available depth matrix ZRMDR are set to the ice layer thicknesses; the matrix ZMAT is initialized to zero; and each level J of WMOVE and TMOVE from 2 to the bottom of the ice profile is set to the value of DELZ and TBAR respectively of the J-1 ice level. The ZMAT matrix represents the depth of each ice layer J that is occupied by ice from level K in the layer movement matrix WMOVE after the layer adjustments are complete. In the 700 loop, starting at the top of the ice profile, an attempt is made to assign each layer of WMOVE in turn to the K,J level of ZMAT. If the calculated value of ZMAT is greater than the available depth ZRMDR of the layer, ZMAT is set to ZRMDR, WMOVE is decremented by ZRMDR, and ZRMDR is set to zero. Otherwise the calculated value of ZMAT is accepted, ZRMDR is decremented by ZMAT, and WMOVE is set to zero.

Finally, the 900 loop is performed over each ice layer J to determine the new layer temperature. The temperature adjustment variable TADD is initialized to zero, and then incremented by the temperature TMOVE of each level K weighted by the corresponding K,J level of ZMAT, and finally by the original layer temperature weighted by the corresponding level of ZRMDR. The layer temperature is reset to TADD normalized by DELZ, and the updating of HTC, begun at the end of the 300 loop, is completed.

6.44.1 Detailed Description

Canadian Terrestrial Ecosystem Model (CTEM) Maintenance Respiration Subroutine.

Autotrophic respiration ($\text{mol CO}_2 \text{ m}^{-2} \text{ s}^{-1}$) is composed of maintenance, R_m , and growth respirations, R_g ,

$$R_a = R_m + R_g.$$

Maintenance respiration accounts for carbon consumed by processes that keep existing plant tissues alive and is a function of environmental stresses. Maintenance respiration is calculated on a half-hourly time step (with photosynthesis) for the leaves, R_{mL} , and at a daily time step for the stem, R_{mS} , and root, R_{mR} , components

$$R_m = R_{mL} + R_{mS} + R_{mR}.$$

Maintenance respiration is generally strongly correlated with nitrogen content **[Reich1998-zr]** **[Ryan1991-ai]**. The current version of CTEM does not explicitly track nitrogen in its vegetation components. Therefore, we adopt the approach of **[Collatz1991-5bc]** **[Collatz1992-jf]** in which the close relation between maximum catalytic capacity of Rubisco, V_m , and leaf nitrogen content is used as a proxy to estimate leaf maintenance respiration,

$$R_{mL} = \varsigma_L V_m f_{25}(Q_{10}d, n) f_{PAR},$$

where ς_L is set to 0.015 and 0.025 for C_3 and C_4 plants, respectively, f_{PAR} scales respiration from the leaf to the canopy level, similar to Eq. (G_canopy)), and the $f_{25}(Q_{10}d, n)$ function accounts for different temperature sensitivities of leaf respiration during day (d) and night (n). **[Pons2003-f26]** and **[Xu2003-d75]** suggest lower temperature sensitivity for leaf respiration during the day compared to night, and therefore we use values of $Q_{10}d = 1.3$ and $Q_{10}n = 2.0$ for day and night, respectively.

Maintenance respiration from the stem and root components is estimated based on PFT-specific base respiration rates (ς_S and ς_R specified at 15 C, $\text{kg C} (\text{kg C})^{-1} \text{ yr}^{-1}$; see also [ctem_params.f90](#)) that are modified to account for temperature response following a Q_{10} function. Maintenance respiration from stem and root components, $R_{m\{S,R\}}$, is calculated as

$$R_{m,i} = 2.64 \times 10^{-6} \varsigma_i l_{v,i} C_i f_{15}(Q_{10}), \quad i = S, R,$$

where $l_{v,i}$ is the live fraction of stem or root component, i.e. the sapwood, and C_i is the stem or root carbon mass (kg C m^{-2}). The constant 2.64×10^{-6} converts units from $\text{kg C m}^{-2} \text{ yr}^{-1}$ to $\text{mol CO}_2 \text{ m}^{-2} \text{ s}^{-1}$. The live sapwood fraction, $l_{v,i}$, for stem or root component is calculated following the CENTURY model **[Parton1996-zv]** as

$$l_{v,i} = \max(0.05, \min[1.0, \exp^{-0.2835C_i}]), \quad i = S, R.$$

The Q_{10} value used in Eq. (r_msr)) is not assumed to be constant but modelled as a function of temperature following **[Joelker2001-uz]** as

$$Q_{10} = 3.22 - 0.046 \left(\frac{15.0 + T_{\{S,R\}}}{1.9} \right),$$

where $T_{\{S,R\}}$ is stem or root temperature (C). Stem temperature is assumed to be the same as air temperature while root temperature is based on the soil temperature weighted by the fraction of roots present in each soil layer **[Arora2003838]**. The calculated Q_{10} value is additionally constrained to be between 1.5 and 4.0.

Growth respiration, R_g ($\text{mol CO}_2 \text{ m}^{-2} \text{ s}^{-1}$), is estimated as a fraction ($\epsilon_g = 0.15$) of the positive gross canopy photosynthetic rate after maintenance respiration has been accounted for

$$R_g = \epsilon_g \max[0, (G_{canopy} - R_m)].$$

Finally, net primary productivity (NPP) is calculated as

$$NPP = G_{canopy} - R_m - R_g.$$

<i>rootmass</i>	root biomass for the 9 pfts in kgc/m^2
<i>rmatctem</i>	fraction of roots in each layer for each pft

Constants and parameters are located in [ctem_params.f90](#)

set the following switch to .true. for using constant temperature independent q10 specified below

q10 - if using a constant temperature independent value, i.e. if consq10 is set to true

initialize required arrays to zero

initialization ends

based on root and stem biomass, find fraction which is live. for stem this would be the sapwood to total wood ratio.

fraction of roots for each vegetation type, for each soil layer, in each grid cell is given by rmatctem (grid cell, veg type, soil layer) which bio2str subroutine calculates. rmatctem can thus be used to find average root temperature for each plant functional type

we assume that stem temperature is same as canopy temperature tcan. using stem and root temperatures we can find their maintenance respirations rates

first find the q10 response function to scale base respiration rate from 15 c to current temperature, we do the stem first.

when finding temperature dependent q10, use temperature which is close to average of actual temperature and the temperature at which base rate is specified

This q10 value is then used with the base rate of respiration (commonly taken at some reference temperature (15 deg c), see Tjoelker et al. 2009 New Phytologist or Atkin et al. 2000 New Phyto for an example.). Long-term acclimation to temperature could be occurring see King et al. 2006 Nature SOM for a possible approach. JM.

Canadian Terrestrial Ecosystem Model (CTEM) Mortality Subroutine.

Functions/Subroutines

- subroutine [mortality](#) (stemmass, rootmass,ailcg, gleafmas,bleafmas,il1,il2, leapnow,iday, sort,fcanctx,

6.45.1 Detailed Description

Canadian Terrestrial Ecosystem Model (CTEM) Mortality Subroutine.

Mortality

The PFT-dependent mortality rate (day^{-1}),

$$m_{\alpha} = m_{intr,\alpha} + m_{ge,\alpha} + m_{bioclim,\alpha} + m_{dist,\alpha},$$

reflects the net effect of four different processes: (1) intrinsic- or age-related mortality, m_{intr} , (2) growth or stress-related mortality, m_{ge} , (3) mortality associated with bioclimatic criteria, $m_{bioclim}$ and (4) mortality associated with disturbances, m_{dist} .

Intrinsic- or age-related mortality uses a PFT-specific maximum age, A_{max} (see also [ctem_params.f90](#)), to calculate an annual mortality rate such that only 1 % of tree PFTs exceed $A_{max,\alpha}$. Intrinsic mortality accounts for processes, whose effect is not explicitly captured in the model including insect damage, hail, wind throw, etc.,

$$m_{intr,\alpha} = 1 - \exp(-4.605/A_{max,\alpha}).$$

Grasses and crops have $m_{intr} = 0$. The annual growth-related mortality m_{ge} is calculated using growth efficiency of a PFT over the course of the previous year following [Prentice1993-xn] and [Sitch2003-847] as

$$m_{ge,\alpha} = \frac{m_{ge,max,\alpha}}{1 + k_m g_{e,\alpha}},$$

where $m_{ge,max}$ represents the PFT-specific maximum mortality rate when no growth occurs (see also [ctem_params.f90](#)). k_m is a parameter set to $0.3 \text{ m}^2 (\text{g C})^{-1}$. g_e is the growth efficiency of the PFT (g C m^{-2}) calculated based on the maximum LAI ($L_{\alpha,max}$; $\text{m}^2 \text{ m}^{-2}$) and the increment in stem and root mass over the course of the previous year (ΔC_S and ΔC_R ; kg C m^{-2} , respectively) [Waring1983-wc]

$$g_{e,\alpha} = 1000 \frac{\max(0, (\Delta C_{S,\alpha} + \Delta C_{R,\alpha}))}{L_{\alpha,max}}.$$

Mortality associated with bioclimatic criteria, $m_{bioclim}$ (0.25 yr^{-1}), is applied when climatic conditions in a grid cell become unfavourable for a PFT to exist and ensures that PFTs do not exist outside their bioclimatic envelopes, as explained in the next section.

The annual mortality rates for m_{intr} , m_{ge} and $m_{bioclim}$ are converted to daily rates and applied at the daily time step of the model, while m_{dist} is calculated by the fire module of the model based on daily area burned for each PFT as summarized in Appendix fire}. In practice, the $\frac{df_{\alpha}}{dt} = -m_{dist,\alpha} f_{\alpha}$ term of Eq. (compact)} is implemented right after area burnt is calculated.

6.45.2 Function/Subroutine Documentation

6.45.2.1 subroutine mortality (real, dimension(ilg,icc) *stemmass*, real, dimension(ilg,icc) *rootmass*, real, dimension(ilg,icc) *ailcg*, real, dimension(ilg,icc) *gleafmas*, real, dimension(ilg,icc) *bleafmas*, integer *il1*, integer *il2*, logical *leapnow*, integer *iday*, integer, dimension(icc) *sort*, real, dimension(ilg,icc) *fcancmx*)

Parameters

<i>il1</i>	il1=1
<i>il2</i>	il2=ilg
<i>iday</i>	day of the year
<i>leapnow</i>	true if this year is a leap year. Only used if the switch 'leap' is true.

<i>rootmass</i>	root mass for each of the 9 ctem pfts, kgc/m^2
<i>gleafmas</i>	green leaf mass for each of the 9 ctem pfts, kgc/m^2
<i>ailcg</i>	green or live lai
<i>bleafmas</i>	brown leaf mass for each of the 9 ctem pfts, kgc/m^2

Constants and parameters are located in [ctem_params.f90](#)

initialize required arrays to zero

initialization ends

at the end of every year, i.e. when iday equals 365, we calculate growth related mortality. rather than using this number to kill plants at the end of every year, this mortality rate is applied gradually over the next year.

calculate growth related mortality using last year's growth efficiency or the new growth efficiency if day is 365 and growth efficiency estimate has been updated above.

convert (1/year) rate into (1/day) rate

calculate intrinsic mortality rate due to aging which implicitly includes effects of frost, hail, wind throw etc. it is assumed that only 1% of the plants exceed maximum age (which is a pft-dependent parameter). to achieve this some fraction of the plants need to be killed every year.

convert (1/year) rate into (1/day) rate

now that we have both growth related and intrinsic mortality rates, lets combine these rates for every pft and estimate litter generated

grid average peat soil heterotrophic respiration subroutine

6.48.1 Detailed Description

Central module for all peatland-related operations.

The peatland module is published in Geoscientific Model Development (Wu et al. 2016) **[Wu2016-zt]**. A copy of the paper is in the Documentation folder of this git repository.

To account for the eco-hydrological and biogeochemical interactions among vegetation, atmosphere and soil in peatlands, the following modifications were made to the coupled CLASS3.6–CTEM2.0 modelling framework:

1. The top soil layer was characterized as a moss layer with a higher heat and hydraulic capacity than a mineral soil layer. The moss layer buffers the exchange of energy and water at the soil surface and regulates the soil temperature and moisture (Turetsky et al. 2012) [Turetsky2012-qh].
2. Three peatland vascular PFTs (evergreen shrubs, deciduous shrubs and sedges) as well as mosses were added to the existing nine CTEM PFTs. These peatland-specific PFTs are adapted to cold climate and inundated soil with optimized plant structure (shoot/root ratio, rooting depth), growth strategy and metabolic acclimations to light, water and temperature.
3. We considered the soil inundation stress on microbial respiration in the litter C pool. The original CTEM assumed that litter respiration was not affected by oxygen deficit as a result of flooding, since litter was always assumed to have access to air. This assumption does not hold for peatlands where high water table positions occur routinely.
4. To provide the framework for future runs coupled to the global earth system model, we separated the soil C balance and heterotrophic respiration (HR) calculations for peatland and non-peatland fractions for each grid cell in the global model. Over the non-peatland fraction, we use the original CTEM approach that aggregates the HR from each PFT weighted by the fractional cover. Over the peatland fraction the soil C pool and decomposition are controlled by the water table position, following the two-compartment approach used in the MWM (St. Hilaire et al. 2010) [St-Hilaire2010-5e9].

The standard configuration of soil layers in CLASS consists of three layers with thickness of 0.10, 0.25, and 3.75 m. Organic soil in CLASS was parameterized by Letts et al. (2000) [Letts2000-pg] as fibric, hemic and sapric peat in the three soil layers respectively, representing fresh, moderately decomposed and highly decomposed organic matter. Tests of CLASS on peatlands revealed improved performance in the energy simulations for fens and bogs with this organic soil parameterization. However, the model overestimated energy and water fluxes at bog surfaces during dry periods due to the neglect of the moss cover (Comer et al., 2000) [Comer2000-mz].

To take into account the interaction amongst the moss and the soil layers and the overlying atmosphere for energy and water transfer, we added a new soil layer 0.10 m thick above the fibric organic soil to represent living and dead peatland bryophytes, such as Sphagnum mosses and true mosses (Bryopsida). The physical characteristics of mosses differ from those of either the shoots or the roots of vascular plants (Rice et al., 2008). In particular, mosses can hold more than 30 g of water per gram of biomass (Robroek et al., 2009). More than 90 % of the moss leaf volume is occupied by the water-holding hyaline cells (Rice et al., 2008), which retain water even when the water table depth declines to 1–10 m below the surface (Hayward and Clymo, 1982).

The parameter values of the moss layer for water and energy properties were derived from a number of recent experiments measuring the hydraulic properties of mosses (Price et al., 2008 [Price2008-fr]; Price and Whittington, 2010; McCarter and Price, 2012). Living mosses range from 2–3 to over 5 cm in height (Rice et al., 2008) and have lower values of dry bulk density and field capacity than fibric peat (Price et al., 2008) [Price2008-fr]. Compared to fibric peat, the saturated hydraulic conductivity of living moss is higher by orders of magnitude (Price et al., 2008) [Price2008-fr] and the thermal conductivity is more affected by the water content (O'Donnell et al., 2009). To fully account for the effect of mosses, we set the depth of the living moss (z_m) within the top soil (i.e. moss) layer to 3 cm for fens and 4 cm for bogs, and interpolated its water content w_m (kg water / (kg dry mass)) from the water content of the overall layer $\theta_{l,1}$ ($\text{m}^3 \text{ water} / (\text{m soil})^3$) and the depth of the living moss:

$$w_m = \frac{z_m \theta_{l,1} \rho_w}{B_m}$$

where the dry moss biomass (B_m) is converted from moss C (C_m) using the standard conversion factor of 0.46 kg C per kg dry biomass, $\theta_{l,1}$ ($\text{m}^3 \text{ water} / \text{m}^3$) is the liquid water content of the top soil layer, and ρ_w is the density of water (1000 kg m^{-3}). The maximum and minimum moss water contents were estimated from a number of observed moss water contents (e.g. Williams and Flanagan, 1998; Robroek et al., 2009). In CLASS, evaporation at the soil surface is controlled by a soil evaporation efficiency coefficient β (Verseghy, 2012). This parameter is calculated from the liquid water content and the field capacity of the first soil layer following Lee and Pielke (1992). For peatlands, β was assumed to be regulated by the relative moisture of the living moss rather than the ratio of relative liquid water content of the first soil layer:

$$\beta = 0.25 \left[1 - \cos \left(\frac{w_m - w_{m,min}}{w_m - w_{m,max}} \right) \right]^2$$

where w_m , $w_{m,max}$, and $w_{m,min}$ are the water content and the maximum and minimum water contents of the living moss in kg water / (kg dry mass).

Canadian Terrestrial Ecosystem Model (CTEM) Phenology, Leaf Turnover & Mortality Subroutine.

Functions/Subroutines

- subroutine [phenology](#) (gleafmas, bleafmas, il1, il2, leapnow, tbar, thliq, wiltsm, fieldsm, ta, anveg, iday, radl, root-temp, rmatctem, stemmass, rootmass, sort, nol2pfts, fcanctx, isand,

6.49.1 Detailed Description

Canadian Terrestrial Ecosystem Model (CTEM) Phenology, Leaf Turnover & Mortality Subroutine.

The leaf phenology parametrization used in CTEM v. 1.0 is described in detail by [Arora2005-6b1]. Changes between version 1.0 and 2.0 are limited to parameter values and the parametrization is briefly described here. There are four different leaf phenological states in which vegetation can be at a given instant: (i) no leaves or dormant, (ii) maximum growth, (iii) normal growth and (iv) leaf fall or harvest. PFTs may go through only some, or all, of these phenological states depending on their deciduousness. A broadleaf cold deciduous tree, for example, transitions through all these four states in a year. In winter, the broadleaf cold deciduous trees are in the no leaves/dormant state; favourable climatic conditions in spring trigger leaf growth and the tree enters the maximum leaf growth state when all the NPP is allocated to leaves to accelerate leaf out; when the LAI reaches a threshold (described below) the tree enters the normal leaf growth state and NPP is also allocated to stem and root components; finally the arrival of autumn triggers leaf fall and the trees go into the leaf fall mode where no carbon is allocated to leaves (but it continues for roots and stems). When all the leaves have been shed, the trees go into the no leaves or dormant state again and the cycle is repeated the next year. The evergreen tree PFTs and the grass PFTs do not enter the leaf fall state and maintain a leaf canopy as long as environmental conditions are favourable. Although drought and cold stress cause accelerated leaf loss compared to the normal leaf turnover from these PFTs, they do not explicitly go into the leaf fall mode where the intent is to lose all leaves in a specified amount of time.

The leaf phenological state transitions are dependent upon environmental conditions. In particular, the transition from no leaves/dormant state to the maximum growth state is based on the carbon-gain approach. CTEM uses *virtual* leaves to assess favourable meteorological conditions for leaf out. The virtual leaves photosynthesize and respire in a manner similar to normal leaves except the carbon gain or loss is not taken into account in vegetation's carbon balance. A positive net leaf photosynthesis rate ($G_{canopy,net}$, Eq. Gnet}) for the virtual leaves over seven consecutive days indicates the arrival of favourable growth conditions and triggers leaf onset and the associated transition from the no leaves/dormant state to the maximum leaf growth state, when the entire positive NPP is allocated to leaves ($a_{fL} = 1, a_{fS} = a_{fR} = 0$). When LAI reaches LAI_{thrs} then the vegetation switches to the normal growth mode and positive NPP is allocated to all three vegetation components – leaves, stem and roots ($a_{fL}, a_{fS}, a_{fR} > 0$). LAI_{thrs} is calculated as

$$LAI_{thrs} = L_f \left[SLA \left(\frac{C_S + C_R}{\eta} \right)^{1/\kappa} \right].$$

The PFT-specific L_f term (see also [ctem_params.f90](#)) calculates LAI_{thrs} to be typically between 40 and 50% of the maximum LAI that a given amount of stem and root biomass can support (based on the terms in the square brackets and Eq. (propwoody)). SLA is the specific leaf area (Eq. sla}). This rule for transition from a maximum to a normal growth state is also used for evergreen tree PFTs and grass PFTs. Similar to LAI_{thrs} , the LAI of virtual leaves is 7.5 % of the maximum LAI a given amount of root and stem biomass can support for tree and crop PFTs and 2.5 % for grass PFTs. In addition, the LAI of virtual leaves is constrained to be, at least, $0.3 m^2 m^{-2}$ for tree PFTs and $0.2 m^2 m^{-2}$ for crop and grass PFTs.

The transition from the normal growth state to the leaf fall state is triggered by unfavourable environmental conditions and shorter day length. Broadleaf deciduous trees transition to the leaf fall state when either: (i) day length is less than 11 h and the rooting zone temperature drops below 11.15 C or (ii) when the rooting zone temperature drops below 8 C regardless of the day length. Needleleaf deciduous trees begin leaf fall after seven consecutive days with daily mean air temperature below -5 C. Leaf fall occurs over a period of 15 days. In the leaf fall state, the vegetation continues carbon allocation to its root and stem components, but not to leaves ($a_{fL} = 0, a_{fS} + a_{fR} = 1$).

Evergreen trees and grasses do not enter the leaf fall state and neither do the broadleaf drought deciduous trees. The implication for the latter PFT is that if the climate changes and the dry season becomes shorter, then the trees will keep their leaves on for a longer period of time since broadleaf drought deciduous trees lose leaves due to soil moisture stress (described below).

The model vegetation is able to transition between the different leaf phenological states in response to changing conditions. For example, a leaf out in spring for broadleaf cold deciduous trees can be interrupted by a cold event when the vegetation goes into a leaf fall state until the return of more favourable conditions.

Leaf litter generation is caused by normal turnover of leaves ($\Omega_N, \text{day}^{-1}$) and also due to cold ($\Omega_C, \text{day}^{-1}$) and drought ($\Omega_D, \text{day}^{-1}$) stress, both of which contribute to seasonality of LAI. For example, the leaf loss associated with drought and reduced photosynthesis during the dry season are the principal causes of the seasonality of LAI for the broadleaf drought deciduous tree PFT.

The conversion of leaf carbon to leaf litter ($D_L, \text{kg C m}^{-2} \text{day}^{-1}$) is expressed as

$$D_L = C_L [1 - \exp(-\Omega_N - \Omega_C - \Omega_D)],$$

where ($\Omega_{N,C,D}, \text{day}^{-1}$) are the leaf loss rates associated with normal turnover of leaves and the cold and drought stress. The rate of normal turnover of leaves is governed by PFT-specific leaf lifespan (τ_L, yr) as $\Omega_N = 1/365\tau_L$ (see also [ctem_params.f90](#)) for PFT specific values of τ_L). The leaf loss rate associated with cold stress (Ω_C) is calculated as

$$\Omega_C = \Omega_{C,max} L_{cold}^3,$$

where $\Omega_{C,max}$ (day^{-1} , see also [ctem_params.f90](#)) is the maximum cold stress loss rate. L_{cold} is a scalar that varies between 0 and 1 as

$$L_{cold} = \begin{cases} 1, & T_a < (T_{cold}^{leaf} - 5) \\ 1 - \frac{T_a - (T_{cold}^{leaf} - 5)}{5}, & T_{cold}^{leaf} > T_a > (T_{cold}^{leaf} - 5) \\ 0, & T_a > T_{cold}^{leaf} \end{cases}$$

where T_{cold}^{leaf} is a PFT-specific temperature threshold below which a PFT experiences damage to its leaves promoting leaf loss (see also [ctem_params.f90](#)) and T_a is the daily mean air temperature ($^{\circ}\text{C}$). The leaf loss rate due to drought stress is calculated in a similar manner

$$\Omega_D = \Omega_{D,max} (1 - \phi_{root})^3,$$

where $\Omega_{D,max}$ (day^{-1} , see also [ctem_params.f90](#)) is the maximum drought stress loss rate and ϕ_{root} (Eq. [deg-soilsat](#)) is the degree of soil saturation in the rooting zone.

6.49.2 Function/Subroutine Documentation

6.49.2.1 subroutine phenolgy (real, dimension(ilg,icc) *gleafmas*, real, dimension(ilg,icc) *bleafmas*, integer *il1*, integer *il2*, logical *leapnow*, real, dimension(ilg,ignd) *tbar*, real, dimension(ilg,ignd) *thliq*, real, dimension(ilg,ignd) *wiltsm*, real, dimension(ilg,ignd) *fieldsm*, real, dimension(ilg) *ta*, real, dimension(ilg,icc) *anveg*, integer *iday*, real, dimension(ilg) *radl*, real, dimension(ilg,icc) *roottemp*, real, dimension(ilg,icc,ignd) *rmatctem*, real, dimension(ilg,icc) *stemmass*, real, dimension(ilg,icc) *rootmass*, integer, dimension(icc) *sort*, integer, dimension(ican) *no12pfts*, real, dimension(ilg,icc) *fcancmx*, integer, dimension(ilg,ignd) *isand*)

Parameters

<i>il1</i>	<i>il1=1</i>
------------	--------------

<i>il2</i>	il2=ilg
<i>iday</i>	day of year
<i>leapnow</i>	true if this year is a leap year. Only used if the switch 'leap' is true.
<i>sort</i>	index for correspondence between 9 pfts and the 12 values in parameters vectors
<i>nol2pfts</i>	number of level 2 ctem pfts
<i>gleafmas</i>	green or live leaf mass in kgc/m^2 , for the 9 pfts
<i>bleafmas</i>	brown or dead leaf mass in kgc/m^2 , for the 9 pfts
<i>ta</i>	air temperature, k
<i>tbar</i>	soil temperature, k
<i>thliq</i>	liquid soil moisture content in 3 soil layers
<i>anveg</i>	net photosynthesis rate of ctem's pfts, $\mu mol\ co2/m2.s$
<i>roottemp</i>	root temperature, which is a function of soil temperature of course, k.
<i>rmatctem</i>	fraction of roots in each soil layer for each pft
<i>stemmass</i>	stem mass for each of the 9 ctem pfts, kgc/m^2
<i>rootmass</i>	root mass for each of the 9 ctem pfts, kgc/m^2
<i>fcancmx</i>	max. fractional coverage of ctem's 9 pfts, but this can be modified by land-use change, and competition between pfts
<i>fieldsm</i>	field capacity soil moisture content both calculated in allocate subroutine
<i>wiltsm</i>	wilting point soil moisture content
<i>radl</i>	latitude in radians

Constants and parameters are located in [ctem_params.f90](#)

initialize required arrays to zero

initialization ends

convert green leaf mass into leaf area index using specific leaf area ($sla, m^2/kgc$) estimated using leaf life span. see bio2str subroutine for more details.

also find threshold lai as a function of stem+root biomass which is used to determine leaf status

using green leaf area index (ailcg) determine the leaf status for each pft. loops 190 and 200 thus initialize lfstatus, if this information is not passed specifically as an initialization quantity.

knowing lfstatus (after initialization above or using value from previous time step) we decide if we stay in a given leaf mode or we move to some other mode.

we start with the "no leaves" mode

add one to pandays(i,j) if daily an is positive, otherwise set it to zero.

if in "no leaves" mode check if an has been positive over last dayschk(j) days to move into "max. growth" mode. if not we stay in "no leaves" mode. also set the chkmode(i,j) switch to 1.

find day length using day of year and latitude. this is to be used for initiating leaf offset for broad leaf dcd trees.

even if pandays criteria has been satisfied do not go into max. growth mode if environmental conditions are such that they will force leaf fall or harvest mode.

needle leaf dcd

broad leaf dcd cld & dry

crops

similar to the way we count no. of days when an is positive, we find no. of days when temperature is below -5 c. we need this to determine if we go into "leaf fall" mode for needle leaf dcd trees.

also estimate no. of days below 8 c. we use these days to decide if its cold enough to harvest crops.

if in "max growth" mode

if mode hasn't been checked and we are in "max. growth" mode, then check if we are above pft-dependent lai threshold. if lai is more then this threshold we move into "normal growth" mode, otherwise we stay in "max growth" mode so that leaves can grow at their max. climate-dependent rate

for dcd trees we also need to go into "leaf fall" mode directly from "max. growth" mode.

ndl dcd

bdl dcd cold

bdl dcd dry

if in "normal growth" mode

if in "normal growth" mode then go through every pft individually and follow set of rules to determine if we go into "fall/harvest" mode

needle leaf evg

needle leaf dcd

broad leaf evg

broad leaf dcd cold we use daylength and roottemp to initiate leaf offset

broad leaf dcd dry we still use daylength and roottemp to initiate leaf offset, for the pathological cases of dry dcd trees being further away from the equator then we can imagine. other wise leaf loss will occur due to drought anyway.

"normal growth" to "fall/harvest" transition for crops is based on specified lai. we harvest if lai of crops reaches a threshold. if lai doesn't reach this threshold (say due to a bad year) we harvest anyway if it starts getting cold, otherwise we don't harvest.

"normal growth" to "max. growth" transition for grasses

if in "fall/harvest" mode

grasses and evg trees do not come into this mode, because they want to stay green if possible. this mode is activated for dcd plants and crops. once in this mode dcd trees loose their leaves and crops are harvested. ndl dcd trees keep loosing their leaves at rate determined by cold stress, bdl dcd trees loose their leaves at a specified rate, and crops are harvested over a period of 15 days. dcd trees and crops stay in "leaf fall/harvest" model until all green leaves are gone at which time they switch into "no leaves" mode, and then wait for the climate to become favourable to go into "max. growth" mode

check that leaf status of all vegetation types in all grid cells has been updated

having decided leaf status for every pft, we now calculate normal leaf turnover, cold and drought stress mortality, and for bdl dcd plants we also calculate specified loss rate if they are in "leaf fall" mode, and for crops we calculate harvest loss, if they are in "harvest" mode.

all these loss calculations will yield leaf litter in kgc/m^2 for the given day for all pfts

normal leaf turn over

for drought stress related mortality we need field capacity and wilting point soil moisture contents, which we calculated in allocate subroutine

estimate drought stress term averaged over the rooting depth for each pft

using this drought stress term and our two vegetation-dependent parameters we find leaf loss rate associated with drought

estimate leaf loss in kgc/m^2 due to drought stress

similar to drgtstrs we find coldstrs for each pft. we assume that max. cold stress related leaf loss occurs when temperature is 5 c or more below pft's threshold

using this cold stress term and our two vegetation-dependent parameters we find leaf loss rate associated with cold cold related leaf loss rate

estimate leaf loss in kgc/m^2 due to cold stress

now that we have all types of leaf losses (due to normal turnover, cold and drought stress, and fall/harvest) we take the losses for grasses and use those to turn live green grass into dead brown grass. we then find the leaf litter from the brown grass which will then go into the litter pool.

we assume life span of brown grass is 10% that of green grass but this is an adjustable parameter.

combine nrmlloss, drgtloss, and coldloss together to get total leaf litter generated, which is what we use to update gleafmass, except for grasses, for which we have already updated gleafmass.

6.50.1 Detailed Description

Canadian Terrestrial Ecosystem Model (CTEM) Phenology, Leaf Turnover & Mortality Subroutine.

The leaf phenology parametrization used in CTEM v. 1.0 is described in detail by [Arora2005-6b1]. Changes between version 1.0 and 2.0 are limited to parameter values and the parametrization is briefly described here. There are four different leaf phenological states in which vegetation can be at a given instant: (i) no leaves or dormant, (ii) maximum growth, (iii) normal growth and (iv) leaf fall or harvest. PFTs may go through only some, or all, of these phenological states depending on their deciduousness. A broadleaf cold deciduous tree, for example, transitions through all these four states in a year. In winter, the broadleaf cold deciduous trees are in the no leaves/dormant state; favourable climatic conditions in spring trigger leaf growth and the tree enters the maximum leaf growth state when all the NPP is allocated to leaves to accelerate leaf out; when the LAI reaches a threshold (described below) the tree enters the normal leaf growth state and NPP is also allocated to stem and root components; finally the arrival of autumn triggers leaf fall and the trees go into the leaf fall mode where no carbon is allocated to leaves (but it continues for roots and stems). When all the leaves have been shed, the trees go into the no leaves or dormant state again and the cycle is repeated the next year. The evergreen tree PFTs and the grass PFTs do not enter the leaf fall state and maintain a leaf canopy as long as environmental conditions are favourable. Although drought and cold stress cause accelerated leaf loss compared to the normal leaf turnover from these PFTs, they do not explicitly go into the leaf fall mode where the intent is to lose all leaves in a specified amount of time.

The leaf phenological state transitions are dependent upon environmental conditions. In particular, the transition from no leaves/dormant state to the maximum growth state is based on the carbon-gain approach. CTEM uses *virtual* leaves to assess favourable meteorological conditions for leaf out. The virtual leaves photosynthesize and respire in a manner similar to normal leaves except the carbon gain or loss is not taken into account in vegetation's carbon balance. A positive net leaf photosynthesis rate ($G_{canopy,net}$, Eq. Gnet}) for the virtual leaves over seven consecutive days indicates the arrival of favourable growth conditions and triggers leaf onset and the associated transition from the no leaves/dormant state to the maximum leaf growth state, when the entire positive NPP is allocated to leaves ($a_{fL} = 1, a_{fS} = a_{fR} = 0$). When LAI reaches LAI_{thrs} then the vegetation switches to the normal growth mode and positive NPP is allocated to all three vegetation components – leaves, stem and roots ($a_{fL}, a_{fS}, a_{fR} > 0$). LAI_{thrs} is calculated as

$$LAI_{thrs} = L_f \left[SLA \left(\frac{C_S + C_R}{\eta} \right)^{1/\kappa} \right].$$

The PFT-specific L_f term (see also [ctem_params.f90](#)) calculates LAI_{thrs} to be typically between 40 and 50% of the maximum LAI that a given amount of stem and root biomass can support (based on the terms in the square brackets and Eq. (propwoody)). SLA is the specific leaf area (Eq. sla). This rule for transition from a maximum to a normal growth state is also used for evergreen tree PFTs and grass PFTs. Similar to LAI_{thrs} , the LAI of virtual leaves is 7.5 % of the maximum LAI a given amount of root and stem biomass can support for tree and crop PFTs and 2.5 % for grass PFTs. In addition, the LAI of virtual leaves is constrained to be, at least, $0.3 m^2 m^{-2}$ for tree PFTs and $0.2 m^2 m^{-2}$ for crop and grass PFTs.

The transition from the normal growth state to the leaf fall state is triggered by unfavourable environmental conditions and shorter day length. Broadleaf deciduous trees transition to the leaf fall state when either: (i) day length is less than 11 h and the rooting zone temperature drops below $11.15 C$ or (ii) when the rooting zone temperature drops below $8 C$ regardless of the day length. Needleleaf deciduous trees begin leaf fall after seven consecutive days with daily mean air temperature below $-5 C$. Leaf fall occurs over a period of 15 days. In the leaf fall state, the vegetation continues carbon allocation to its root and stem components, but not to leaves ($a_{fL} = 0$, $a_{fS} + a_{fR} = 1$). Evergreen trees and grasses do not enter the leaf fall state and neither do the broadleaf drought deciduous trees. The implication for the latter PFT is that if the climate changes and the dry season becomes shorter, then the trees will keep their leaves on for a longer period of time since broadleaf drought deciduous trees lose leaves due to soil moisture stress (described below).

The model vegetation is able to transition between the different leaf phenological states in response to changing conditions. For example, a leaf out in spring for broadleaf cold deciduous trees can be interrupted by a cold event when the vegetation goes into a leaf fall state until the return of more favourable conditions.

Leaf litter generation is caused by normal turnover of leaves (Ω_N , day^{-1}) and also due to cold (Ω_C , day^{-1}) and drought (Ω_D , day^{-1}) stress, both of which contribute to seasonality of LAI. For example, the leaf loss associated with drought and reduced photosynthesis during the dry season are the principal causes of the seasonality of LAI for the broadleaf drought deciduous tree PFT.

The conversion of leaf carbon to leaf litter (D_L , $kg C m^{-2} day^{-1}$) is expressed as

$$D_L = C_L [1 - \exp(-\Omega_N - \Omega_C - \Omega_D)],$$

where ($\Omega_{N,C,D}$, day^{-1}) are the leaf loss rates associated with normal turnover of leaves and the cold and drought stress. The rate of normal turnover of leaves is governed by PFT-specific leaf lifespan (τ_L , yr) as $\Omega_N = 1/365\tau_L$ (see also [ctem_params.f90](#)) for PFT specific values of τ_L). The leaf loss rate associated with cold stress (Ω_C) is calculated as

$$\Omega_C = \Omega_{C,max} L_{cold}^3,$$

where $\Omega_{C,max}$ (day^{-1} , see also [ctem_params.f90](#)) is the maximum cold stress loss rate. L_{cold} is a scalar that varies between 0 and 1 as

$$L_{cold} = \begin{cases} 1, & T_a < (T_{cold}^{leaf} - 5) \\ 1 - \frac{T_a - (T_{cold}^{leaf} - 5)}{5}, & T_{cold}^{leaf} > T_a > (T_{cold}^{leaf} - 5) \\ 0, & T_a > T_{cold}^{leaf} \end{cases}$$

where T_{cold}^{leaf} is a PFT-specific temperature threshold below which a PFT experiences damage to its leaves promoting leaf loss (see also [ctem_params.f90](#)) and T_a is the daily mean air temperature (C). The leaf loss rate due to drought stress is calculated in a similar manner

$$\Omega_D = \Omega_{D,max} (1 - \phi_{root})^3,$$

where $\Omega_{D,max}$ (day^{-1} , see also [ctem_params.f90](#)) is the maximum drought stress loss rate and ϕ_{root} (Eq. $deg-soilsat$) is the degree of soil saturation in the rooting zone.

6.50.2 Function/Subroutine Documentation

6.50.2.1 subroutine phenolgy (real, dimension(ilg,icc) *gleafmas*, real, dimension(ilg,icc) *bleafmas*, integer *il1*, integer *il2*, logical *leapnow*, real, dimension(ilg,ignd) *tbar*, real, dimension(ilg,ignd) *thliq*, real, dimension(ilg,ignd) *THLW*, real, dimension(ilg,ignd) *THFC*, real, dimension(ilg) *ta*, real, dimension(ilg,icc) *anveg*, integer *iday*, real, dimension(ilg) *radl*, real, dimension(ilg,icc) *roottemp*, real, dimension(ilg,icc,ignd) *rmatctem*, real, dimension(ilg,icc) *stemmass*, real, dimension(ilg,icc) *rootmass*, integer, dimension(icc) *sort*, integer, dimension(ican) *no12pfts*, real, dimension(ilg,icc) *fcancmx*, integer, dimension(ilg,ignd) *isand*)

Parameters

<i>il1</i>	il1=1
<i>il2</i>	il2=ilg
<i>iday</i>	day of year
<i>leapnow</i>	true if this year is a leap year. Only used if the switch 'leap' is true.
<i>sort</i>	index for correspondence between 9 pfts and the 12 values in parameters vectors
<i>nol2pfts</i>	number of level 2 ctem pfts
<i>gleafmas</i>	green or live leaf mass in
<i>bleafmas</i>	brown or dead leaf mass in
<i>ta</i>	air temperature, k
<i>tbar</i>	soil temperature, k
<i>thliq</i>	liquid soil moisture content in 3 so
<i>anveg</i>	net photosynthesis rate of ctem's pfts, $\mu\text{mol co}_2/\text{m}^2.\text{s}$
<i>roottemp</i>	root temperature, which is a function of soil temperature of course, k.
<i>rmatctem</i>	fraction of roots in each soil layer for each pft
<i>stemmass</i>	stem mass for each of the 9 ctem pfts, kgc/m^2
<i>rootmass</i>	root mass for each of the 9 ctem pfts, kgc/m^2
<i>fcancmx</i>	max. fractional coverage of ctem's 9 pfts, but this can be modified by land-use change, and competition between pfts
<i>thfc</i>	field capacity soil moisture content both calculated in allocate subroutine
<i>thlw</i>	wilting point soil moisture content
<i>radl</i>	latitude in radians

Constants and parameters are located in [ctem_params.f90](#)

initialize required arrays to zero

initialization ends

convert green leaf mass into leaf area index using specific leaf area ($\text{sla}, \text{m}^2/\text{kgc}$) estimated using leaf life span. see bio2str subroutine for more details.

also find threshold lai as a function of stem+root biomass which is used to determine leaf status

using green leaf area index (ailcg) determine the leaf status for each pft. loops 190 and 200 thus initialize lfstatus, if this this information is not passed specifically as an initialization quantity.

knowing lfstatus (after initialization above or using value from from previous time step) we decide if we stay in a given leaf mode or we move to some other mode.

we start with the "no leaves" mode

add one to pandays(i,j) if daily an is positive, otherwise set it to zero.

if in "no leaves" mode check if an has been positive over last dayschk(j) days to move into "max. growth" mode. if not we stay in "no leaves" mode. also set the chkmode(i,j) switch to 1.

find day length using day of year and latitude. this is to be used for initiating leaf offset for broad leaf dcd trees.

even if pandays criteria has been satisfied do not go into max. growth mode if environmental conditions are such that they will force leaf fall or harvest mode.

crops

if in "max growth" mode

if mode hasn't been checked and we are in "max. growth" mode, then check if we are above pft-dependent lai threshold. if lai is more then this threshold we move into "normal growth" mode, otherwise we stay in "max growth" mode so that leaves can grow at their max. climate-dependent rate

for dcd trees we also need to go into "leaf fall" mode directly from "max. growth" mode.

ndl dcd

bdl dcd cold

bdl dcd dry

if in "normal growth" mode

if in "normal growth" mode then go through every pft individually and follow set of rules to determine if we go into "fall/harvest" mode

needle leaf dcd

broad leaf evg

broad leaf dcd cold we use daylength and roottemp to initiate leaf offset

broad leaf dcd dry we still use daylength and roottemp to initiate leaf offset, for the pathological cases of dry dcd trees being further away from the equator then we can imagine. other wise leaf loss will occur due to drought anyway.

"normal growth" to "fall/harvest" transition for crops is based on specified lai. we harvest if lai of crops reaches a threshold. if lai doesn't reach this threshold (say due to a bad year) we harvest anyway if it starts getting cold, otherwise we don't harvest.

add a branch for icc =12, j6, 7 = shrubs, j 8,9 = crops, j10,11,12
= grasses, YW April 15, 2015 -----\

"normal growth" to "max. growth" transition for grasses

if in "fall/harvest" mode

grasses and evg trees do not come into this mode, because they want to stay green if possible. this mode is activated for dcd plants and crops. once in this mode dcd trees loose their leaves and crops are harvested. ndl dcd trees keep loosing their leaves at rate determined by cold stress, bdl dcd trees loose their leaves at a specified rate, and crops are harvested over a period of 15 days. dcd trees and crops stay in "leaf fall/harvest" model until all green leaves are gone at which time they switch into "no leaves" mode, and then wait for the climate to become favourable to go into "max. growth" mode

check that leaf status of all vegetation types in all grid cells has been updated

having decided leaf status for every pft, we now calculate normal leaf turnover, cold and drought stress mortality, and for bdl dcd plants we also calculate specified loss rate if they are in "leaf fall" mode, and for crops we calculate harvest loss, if they are in "harvest" mode.

all these loss calculations will yield leaf litter in kgc/m^2 for the given day for all pfts

normal leaf turn over

for drought stress related mortality we need field capacity and wilting point soil moisture contents, which we calculated in allocate subroutine

estimate drought stress term averaged over the rooting depth for each pft

using this drought stress term and our two vegetation-dependent
parameters we find leaf loss rate associated with drought

estimate leaf loss in kgc/m^2 due to drought stress

similar to drgtstrs we find coldstrs for each pft. we assume that max. cold stress related leaf loss occurs when temperature is 5 c or more below pft's threshold

using this cold stress term and our two vegetation-dependent parameters we find leaf loss rate associated with cold cold related leaf loss rate

estimate leaf loss in kgc/m^2 due to cold stress

now that we have all types of leaf losses (due to normal turnover, cold and drought stress, and fall/harvest) we take the losses for grasses and use those to turn live green grass into dead brown grass. we then find the leaf litter from the brown grass which will then go into the litter pool.

we assume life span of brown grass is 10% that of green grass but this is an adjustable parameter.

combine nrmlloss, drgtloss, and coldloss together to get total leaf litter generated, which is what we use to update gleafmass, except for grasses, for which we have already updated gleafmass.

6.51.1 Detailed Description

CANADIAN TERRESTRIAL ECOSYSTEM MODEL (CTEM) PHOTOSYNTHESIS SUBROUTINE.

Photosynthesis and canopy conductance

Net photosynthesis

All biogeochemical processes in CTEM are simulated at a daily time step except gross photosynthetic uptake and associated calculation of canopy conductance, which are simulated on a half hour time step with CLASS. The photosynthesis module of CTEM calculates the net canopy photosynthesis rate, which, together with atmospheric CO_2 concentration and vapour pressure or relative humidity, is used to calculate canopy conductance. This canopy conductance is then used by CLASS in its energy and water balance calculations.

The photosynthesis parametrization is based upon the approach of [Farquhar1980-96e] and [Collatz1991-5bc] [Collatz1992-jf] as implemented in SiB2 [Sellers1996-bh] and MOSES [Cox1999-ia] with some minor modifications as described in [Arora2003-3b7]. [Arora2003-3b7] outlines four possible configurations for the model based on choice of a *big-leaf* or *two-leaf* (sunlight and shaded leaves) mode and stomatal conductance formulations based on either [Ball1987-ou] or [Leuning1995-ab]. The [Ball1987-ou] formulation uses relative humidity while [Leuning1995-ab] uses vapour pressure deficit in calculation of canopy conductance. While the model remains capable of all four possible configurations, in practice, the model is usually run using the big-leaf parametrization with the stomatal conductance formulation of [Leuning1995-ab], which is the configuration described here. The original description of the CTEM photosynthesis parametrization in [Arora2003-3b7] did not include discussion of all the PFTs simulated by CTEM, which we expand upon here and also include changes to the parametrization since version 1.0.

The gross leaf photosynthesis rate, G_o , depends upon the maximum assimilation rate allowed by the light ($J_{e\$}$), Rubisco (J_c) and transport capacity (J_s). The limitation placed on G_o by the amount of available light is calculated as ($mol CO_2 m^{-2} s^{-1}$)

$$J_e = \{ \varepsilon (1 - \nu) I \left[\frac{c_i - \Gamma}{c_i + 2\Gamma} \right], \quad C_3plants \varepsilon (1 - \nu) I, \quad C_4plants,$$

where I is the incident photosynthetically active radiation (PAR ; $mol photons m^{-2} s^{-1}$), ν is the leaf scattering coefficient, with values of 0.15 and 0.17 for C_3 and C_4 plants, respectively, and ε is the quantum efficiency ($mol CO_2 (mol photons)^{-1}$; values of 0.08 and 0.04 are used for C_3 and C_4 plants, respectively). c_i is the partial pressure of CO_2 in the leaf interior (Pa) and Γ is the CO_2 compensation point (Pa) (described below).

The Rubisco enzyme limited photosynthesis rate, J_c , is given by

$$J_c = \left\{ V_m \left[\frac{c_i - \Gamma}{c_i + K_c(1 + O_a/K_o)} \right], \quad C_3plants V_m, C_4plants, \right.$$

where V_m is the maximum catalytic capacity of Rubisco ($mol CO_2 m^{-2} s^{-1}$), adjusted for temperature and soil moisture, as described below. K_o and K_c are the Michaelis–Menten constants for O_2 and CO_2 , respectively. O_a is the partial pressure (Pa) of oxygen.

The transport capacity (J_s) limitation determines the maximum capacity to transport the products of photosynthesis for C_3 plants, while for C_4 plants it represents CO_2 limitation

$$J_s = \begin{cases} 0.5V_m, C_3plants \\ 2 \times 10^4 V_m \frac{c_i}{p}, C_4plants \end{cases}$$

where p is surface atmospheric pressure (Pa).

V_m is calculated as

$$V_m = \frac{V_{max} f_{25}(2.0) S_{root}(\theta) \times 10^{-6}}{[1 + \exp 0.3(T_c - T_{high})][1 + \exp 0.3(T_{low} - T_c)]},$$

where T_c is the canopy temperature (C) and T_{low} and T_{high} are PFT-dependent lower and upper temperature limits for photosynthesis (see also [ctem_params.f90](#)). f_{25} is the standard Q_{10} function at $25 C$ ($f_{25}(Q_{10}) = Q_{10}^{(0.1(T_c - 25))}$) and V_{max} is the PFT-dependent maximum rate of carboxylation by the enzyme Rubisco ($mol CO_2 m^{-2} s^{-1}$; see also [ctem_params.f90](#)). The constant 10^{-6} converts V_{max} from units of $\mu mol CO_2 m^{-2} s^{-1}$ to $mol CO_2 m^{-2} s^{-1}$.

The influence of soil moisture stress is simulated via $S_{root}(\theta)$, which represents a soil moisture stress term formulated as

$$S_{root}(\theta) = \sum_{i=1}^g S(\theta_i) r_i,$$

$$S(\theta_i) = [1 - \{1 - \phi_i\}]^{\varrho},$$

where $S_{root}(\theta)$ is calculated by weighting $S(\theta_i)$ with the fraction of roots, r_i , in each soil layer i and ϱ is a PFT-specific sensitivity to soil moisture stress (unitless; see also [ctem_params.f90](#)). ϕ_i is the degree of soil saturation (soil wetness) given by

$$\phi_i(\theta_i) = \max \left[0, \min \left(1, \frac{\theta_i - \theta_{i,wilt}}{\theta_{i,field} - \theta_{i,wilt}} \right) \right],$$

where θ_i is the volumetric soil moisture ($m^3 water (m^3 soil)^{-1}$) of the i th soil layer and $\theta_{i,field}$ and $\theta_{i,wilt}$ the soil moisture at field capacity and wilting point, respectively.

The CO_2 compensation point (Γ) is the CO_2 partial pressure where photosynthetic uptake equals the leaf respiratory losses (used in Eqs. J_e and J_c). Γ is zero for C_4 plants but is sensitive to oxygen partial pressure for C_3 plants as

$$\Gamma = \begin{cases} \frac{O_a}{2\sigma}, C_3plants \\ 0, C_4plants, \end{cases}$$

where σ is the selectivity of Rubisco for CO_2 over O_2 (unitless), estimated by $\sigma = 2600 f_{25}(0.57)$. The CO_2 (K_c) and O_2 (K_o) Michaelis–Menten constants used in Eq. (J_c) are determined via

$$K_c = 30 f_{25}(2.1), K_o = 3 \times 10^4 f_{25}(1.2).$$

Given the light (J_e), Rubisco (J_c) and transportation capacity (J_s) limiting rates, the leaf-level gross photosynthesis rate, G_o ($mol CO_2 m^{-2} s^{-1}$), is then determined following a minimization based upon smallest roots of the following two quadratic equations

$$J_p = \frac{(J_c + J_e) \pm \sqrt{(J_c + J_e)^2 - 4\beta_1(J_c + J_e)}}{2\beta_1}, G_o = \frac{(J_p + J_s) \pm \sqrt{(J_p + J_s)^2 - 4\beta_2(J_p + J_s)}}{2\beta_2},$$

where β_1 is 0.95 and β_2 is 0.99. When soil moisture stress is occurring, both the J_s and J_c terms are reduced since the V_m term (Eq. V_m) includes the effect of soil moisture stress through the $S(\theta)$ term and this reduces the leaf-level gross photosynthesis rate.

The current version of CTEM does not include nutrient constraints on photosynthesis and, as a result, increasing atmospheric CO_2 concentration leads to unconstrained increase in photosynthesis. In natural ecosystems, however, down regulation of photosynthesis occurs due to constraints imposed by availability of nitrogen, as well as phosphorus. To capture this effect, CTEM uses a nutrient limitation term, based on experimental plant growth studies, to down regulate the photosynthetic response to elevated CO_2 concentrations [Arora2009-9bc]. The parametrization, and its rationale, are fully described in [Arora2009-9bc] but the basic relations are summarized here. The leaf-level gross photosynthetic rate is scaled by the down-regulation term, Ξ_N , to yield the nutrient limited leaf level gross photosynthetic rate as

$$G_{o,N-limited} = \Xi_N G_o, \Xi_N = \frac{1 + \gamma_{gd} \ln(c_a/c_0)}{1 + \gamma_g \ln(c_a/c_0)},$$

where c_a is the atmospheric CO_2 concentration in ppm, c_0 is the pre-industrial CO_2 concentration (285.0 ppm), γ_g is 0.95 [Arora2009-9bc]. A value of γ_{gd} lower than γ_g ensures that Ξ_N gradually decreases from its pre-industrial value of one as c_a increases to constrain the rate of increase of photosynthesis with rising atmospheric CO_2 concentrations. CTEM v. 2.0 uses a γ_{gd} value of 0.30 (unitless).

Finally, the leaf-level gross photosynthesis rate, $G_{o,N-limited}$ is scaled up to the canopy-level, G_{canopy} , by considering the exponential vertical profile of radiation along the depth of the canopy as

$$G_{canopy} = G_{o,N-limited} f_{PAR}, f_{PAR} = \frac{1}{k_n} (1 - \exp^{-k_n LAI}),$$

which yields the gross primary productivity (G_{canopy} , GPP). k_n is the extinction coefficient that describes the nitrogen and time-mean photosynthetically absorbed radiation (PAR) profile along the depth of the canopy (see also [ctem_params.f90](#)) [Ingestad1986-td] [Field1986-kd], and LAI ($m^2 leaf (m^2 ground)^{-1}$) is the leaf area index.

The net canopy photosynthetic rate, $G_{canopy,net}$ ($mol CO_2 m^{-2} s^{-1}$), is calculated by subtracting canopy leaf maintenance respiration costs (R_{mL} ; see Sect. maint)) as

$$G_{canopy,net} = G_{canopy} - R_{mL}.$$

Coupling of photosynthesis and canopy conductance

When using the [Leuning1995-ab] approach for photosynthesis–canopy conductance coupling, canopy conductance (g_c ; $mol m^{-2} s^{-1}$) is expressed as a function of the net canopy photosynthesis rate, $G_{canopy,net}$, as

$$g_c = m \frac{G_{canopy,net} p}{(c_s - \Gamma)} \frac{1}{(1 + V/V_o)} + b LAI$$

where p is the surface atmospheric pressure (Pa), the parameter m is set to 9.0 for needle-leaved trees, 12.0 for other C_3 plants and 6.0 for C_4 plants, parameter b is assigned the values of 0.01 and 0.04 for C_3 and C_4 plants, respectively. V is the vapour pressure deficit (Pa) and the parameter V_o is set to 2000 Pa for trees and 1500 Pa for crops and grasses. The partial pressure of CO_2 at the leaf surface, c_s , is found via

$$c_s = c_{ap} - \frac{1.37 G_{canopy,net} p}{g_b}.$$

Here, c_{ap} is the atmospheric CO_2 partial pressure (Pa) and g_b is the aerodynamic conductance estimated by CLASS ($mol m^{-2} s^{-1}$). The intra-cellular CO_2 concentration required in Eqs. (J_e)–(J_s)) is calculated as

$$c_i = c_s - \frac{1.65 G_{canopy,net} p}{g_c}.$$

Since calculations of $G_{canopy,net}$ and c_i depend on each other, the photosynthesis–canopy conductance equations need to be solved iteratively. The initial value of c_i used in calculation of $G_{canopy,net}$ is the value from the previous time step or, in its absence, c_i is assumed to be $0.7 c_{ap}$.

Canopy (g_c) and aerodynamic (g_b) conductance used in above calculations are expressed in units of $mol\ CO_2\ m^{-2}\ s^{-1}$ but can be converted to the traditional units of $m\ s^{-1}$ as follows

$$g_c(m\ s^{-1}) = 0.0224 \frac{T_c}{T_f} \frac{p_0}{p} g_c(mol\ m^{-2}\ s^{-1}),$$

where p_0 is the standard atmospheric pressure (101 325 Pa) and T_f is freezing temperature (273.16 K).

1. SINGLE-LEAF & TWO-LEAF COMBINED VERSION, CAN USE EITHER APPROACH
2. CAN USE EITHER BWB OR LEUNING TYPE STOMATAL CONDUCTANCE FORMULATION
3. ALSO, CAN USE SMOOTHED AVERAGE OF THE 3 LIMITING RATES, MIN. OF THE 3 LIMITING RATES, OR MIN. OF LIGHT AND RUBSICO RATES.

CLASS' 4 MAJOR VEGETATION TYPES ARE

1. NEEDLE LEAF OR TALL CONIFEROUS (C3, DECIDUOUS AND EVERGREEN)
2. BROAD LEAF (C3, DECD. AND EVRG.)
3. ARABLE & CROPS - (BOTH C3 AND C4)
4. GRASSES, TUNDRA, ETC. (BOTH C3 AND C4)

BUT FOR PHOTOSYNTHESIS WE NEED TO MAKE DISTINCTION BETWEEN C3 AND C4, AND DECIDUOUS AND EVERGREEN. SO THESE 4 VEGETATION TYPES GET CONVERTED INTO THE FOLLOWING 9

1. NEEDLE LEAF EVERGREEN, C3
2. NEEDLE LEAF DECIDUOUS, C3
3. BROAD LEAF EVERGREEN, C3
4. BROAD LEAF COLD DECIDUOUS, C3
5. BROAD LEAF DRY DECIDUOUS, C3
6. C3 CROP
7. C4 CROP
8. C3 GREEN GRASS
9. C4 GREEN GRASS

INPUTS

NOL2MAX - NUMBER OF LEVEL 2 CTEM PFTs

6.51.2 Function/Subroutine Documentation

6.51.2.1 subroutine `phtsyn3` (real, dimension(ilg,icc) *AILCG*, real, dimension(ilg,icc) *FCANC*, real, dimension(ilg) *TCAN*, real, dimension(ilg) *CO2CONC*, real, dimension(ilg) *PRESSG*, real, dimension(ilg) *FC*, real, dimension(ilg) *CFLUX*, real, dimension(ilg) *QA*, real, dimension(ilg) *QSWV*, integer *IC*, real, dimension(ilg,ig) *THLIQ*, integer, dimension(ilg,ig) *ISAND*, real, dimension(ilg) *TA*, real, dimension(ilg,icc,ig) *RMAT*, real, dimension(ilg) *COSZS*, real, dimension(ilg) *XDIFFUS*, integer *ILG*, integer *IL1*, integer *IL2*, integer *IG*, integer *ICC*, integer *ISNOW*, real, dimension(ilg,icc) *SLAI*, real, dimension(ilg,ig) *THFC*, real, dimension(ilg,ig) *THLW*, real, dimension(ilg,icc) *FCANCMX*, integer *L2MAX*, integer, dimension(ic) *NOL2PFTS*)

Parameters

<i>ilg</i>	NO. OF GRID CELLS IN LATITUDE CIRCLE
<i>ic</i>	NO. OF CLASS VEGETATION TYPES, 4
<i>il1</i>	IL1=1
<i>il2</i>	IL2=ILG
<i>ig</i>	NO. OF SOIL LAYERS, 3
<i>icc</i>	NO. OF CTEM's PFTs, CURRENTLY 9
<i>isnow</i>	INTEGER (0 or 1) TELLING IF PHTSYN IS TO BE RUN OVER CANOPY OVER SNOW OR CANOPY OVER GROUND SUBAREA

<i>l2max</i>	MAX. NUMBER OF LEVEL 2 PFTs
<i>fcanc</i>	FRACTIONAL COVERAGE OF CTEM's 9 PFTs
<i>ailcg</i>	GREEN LEAF AREA INDEX FOR USE BY PHOTOSYNTHESIS, M^2/M^2
<i>tcn</i>	CANOPY TEMPERATURE, KELVIN
<i>fc</i>	SUM OF ALL FCANC OVER A GIVEN SUB-AREA
<i>cflux</i>	AERODYNAMIC CONDUCTANCE, M/S
<i>slai</i>	SCREEN LEVEL HUMIDITY IN KG/KG - STORAGE LAI. THIS LAI IS USED FOR PHTSYN EVEN IF ACTUAL LAI IS ZERO. ESTIMATE OF NET PHOTOSYNTHESIS BASED ON S↔ LAI IS USED FOR INITIATING LEAF ONSET. SEE PHENOLGY SUBROUTINE FOR MORE DETAILS.
<i>co2conc</i>	ATMOS. CO_2 IN PPM, AND THEN CONVERT IT TO PARTIAL PRESSURE, PASCALS, CO_2A , FOR USE IN THIS SUBROUTINE
<i>pressg</i>	ATMOS. PRESSURE, PASCALS
<i>qswv</i>	ABSORBED VISIBLE PART OF SHORTWAVE RADIATION, W/M^2
<i>ta</i>	AIR TEMPERATURE IN KELVINS
<i>rmat</i>	FRACTION OF ROOTS IN EACH LAYER (grid cell, vegetation, layer)
<i>thliq</i>	LIQUID MOIS. CONTENT OF 3 SOIL LAYERS
<i>thfc</i>	SOIL FIELD CAPACITY.
<i>thlw</i>	SOIL WILT CAPACITY.
<i>fcancmx</i>	MAX. FRACTIONAL COVERAGES OF CTEM's 8 PFTs. THIS IS DIFFERENT FROM F↔ CANC AND FCANCs (WHICH MAY VARY WITH SNOW DEPTH). FCANCMX DOESN'T CHANGE, UNLESS OF COURSE ITS CHANGED BY LAND USE CHANGE OR DYNAMIC VEGETATION.
<i>coszs</i>	COS OF ZENITH ANGLE
<i>xdiffus</i>	FRACTION OF DIFFUSED PAR
<i>isand</i>	SAND INDEX.

IF LAI IS LESS THAN SLAI THAN WE USE STORAGE LAI TO PHOTOSYNTHESIZE. HOWEVER, WE DO NOT USE THE STOMATAL RESISTANCE ESTIMATED IN THIS CASE, BECAUSE STORAGE LAI IS AN IMAGINARY LAI, AND WE SET STOMATAL RESISTANCE TO ITS MAX. NOTE THAT THE CONCEPT OF STORAGE/↔ IMAGINARY LAI IS USED FOR PHENOLOGY PURPOSES AND THIS IMAGINARY LAI ACTS AS MODEL SEEDS.

SET MIN. AND MAX. VALUES FOR STOMATAL CONDUCTANCE. WE MAKE SURE THAT MAX. STOMATAL RESISTANCE IS AROUND 5000 S/M AND MIN. STOMATAL RESISTANCE IS 51 S/M.

IF WE ARE USING LEUNING TYPE PHOTOSYNTHESIS-STOMATAL CONDUCTANCE COUPLING WE NEE↔ D VAPOR PRESSURE DEFICIT AS WELL. CALCULATE THIS FROM THE RH AND AIR TEMPERATURE WE HAVE. WE FIND E_{SAT} , E , AND VPD IN PASCALS.

ESTIMATE PARTIAL PRESSURE OF CO_2 AND IPAR

CONVERT CO_2CONC FROM PPM TO PASCALS

CHANGE PAR FROM W/M^2 TO $MOL/M^2.S$

SUNLIT PART GETS BOTH DIRECT AND DIFFUSED, WHILE THE SHADED PART GETS ONLY DIFFUSED

FOR TWO-LEAF MODEL FIND K_b AS A FUNCTION OF $COSZS$ AND LEAF ANGLE DISTRIBUTION (VEGETA↔ TION DEPENDENT)

MAKE SURE $-0.4 < CHI < 0.6$

MAKE VALUES CLOSE TO ZERO EQUAL TO 0.01

ALSO FIND SUNLIT AND SHADED LAI

FOLLOWING FEW LINES TO MAKE SURE THAT ALL LEAVES ARE SHADED WHEN $XDIFFUS$ EQUALS 1. NOT DOING SO GIVES ERRATIC RESULTS WHEN TWO LEAF OPTION IS USED

FIND F_{PAR} - FACTOR FOR SCALING PHOTOSYNTHESIS TO CANOPY BASED ON ASSUMPTION THAT N↔ ITROGEN IS OPTIMALLY DISTRIBUTED. THE TWO-LEAF MODEL IS NOT THAT DIFFERENT FROM THE SI↔ NGLE-LEAF MODEL. ALL WE DO IS USE TWO SCALING FACTORS (I.E. SCALING FROM LEAF TO CANOPY) INSTEAD OF ONE, AND THUS PERFORM CALCULATIONS TWICE, AND IN THE END ADD CONDUCTANCE AND NET PHOTOSYNTHESIS FROM THE TWO LEAVES TO GET THE TOTAL.

IF ALL RADIATION IS DIFFUSED, THEN ALL LEAVES ARE SHADED, AND WE ADJUST FPARs ACCORDINGLY. WITHOUT THIS THE TWO LEAF MODELS MAY BEHAVE ERRATICALLY

FIND $V_{max,canopy}$, THAT IS V_{max} SCALED BY LAI FOR THE SINGLE LEAF MODEL

———— Changing V_{max} seasonally —————

Based on [Bauerle2012-c29] and [Alton2017-pd] there is good evidence for the V_{max} varying throughout the season for deciduous tree species. We are adopting a parameterization based upon their paper with some differences. We don't apply it to evergreens like they suggest. Their paper had only one evergreen species and other papers ([Miyazawa2006-so]) don't seem to back that up. Grasses and crops are also not affected by the dayl. [Alton2017-pd] seems to indicate that all PFTs except BDL-EVG tropical should vary intra-annually (see their figure 8).

The two leaf is assumed to be affect by the insolation seasonal cycle the same for each sun/shade leaf

———— Changing V_{max} seasonally —————///

FIND $V_{m,unstressed}$ (DUE TO WATER) BUT STRESSED DUE TO TEMPERATURE

ASSUMING THAT SUNLIT AND SHADED TEMPERATURES ARE SAME

CALCULATE SOIL MOIS STRESS TO ACCOUNT FOR REDUCTION IN PHOTOSYN DUE TO LOW SOIL MOI-
STURE, THREE STEPS HERE -> 1. FIND WILTING POINT AND FIELD CAPACITY SOIL MOIS. CONTENT FOR ALL THREE LAYERS.

1. USING THESE FIND THE SOIL MOISTURE STRESS TERM FOR ALL THREE LAYERS, AND 3. AV-
ERAGE THIS SOIL MOISTURE STRESS TERM OVER THE 3 LAYERS USING FRACTION OF ROOTS
PRESENT IN EACH LAYER FOR EACH PFT. NOTE THAT WHILE SOIL MOISTURE IS UNIFORM OVER
AN ENTIRE GCM GRID CELL, THE SOIL MOISTURE STRESS FOR EACH PFT IS NOT BECAUSE OF
DIFFERENCES IN ROOT DISTRIBUTION.

WILTING POINT CORRESPONDS TO MATRIC POTENTIAL OF 150 M FIELD CAPACITY CORRESPONDS TO
HYDARULIC CONDUCTIVITY OF 0.10 MM/DAY -> 1.157×10^{-9} M/S

USE SOIL MOISTURE FUNCTION TO MAKE $V_{m,unstressed}$ -> V_m STRESSED

FIND TEMPERATURE DEPENDENT PARAMETER VALUES

FIND RUBISCO SPECIFICITY FOR $C O_2$ RELATIVE TO O_2 - SIGMA

FIND $C O_2$ COMPENSATION POINT USING RUBISCO SPECIFICITY - TGAMMA. KEEP IN MIND THAT $C O_2$
COMPENSATION POINT FOR C4 PLANTS IS ZERO, SO THE FOLLOWING VALUE IS RELEVANT FOR C3
PLANTS ONLY

ESTIMATE MICHELIS-MENTON CONSTANTS FOR $C O_2$ (K_c) and O_2 (K_o) TO BE USED LATER FOR ESTIM-
ATING RUBISCO LIMITED PHOTOSYNTHETIC RATE

CHOOSE A VALUE OF INTERCELLULAR $C O_2$ CONCENTRATION ($C O_{2i}$) IF STARTING FOR THE FIRST TI-
ME, OR USE VALUE FROM THE PREVIOUS TIME STEP

ESTIMATE RUBISCO LIMITED PHOTOSYNTHETIC RATE

ESTIMATE PHOTOSYNTHETIC RATE LIMITED BY AVAILABLE LIGHT

ESTIMATE PHOTOSYNTHETIC RATE LIMITED BY TRANSPORT CAPACITY

INCLUDE NUTRIENT LIMITATION EFFECT BY DOWN-REGULATING PHOTOSYNTHESIS N_EFFECT DECR-
EASES FROM 1.0 AS $C O_2$ INCREASES ABOVE 288 PPM.

LIMIT N_EFFECT TO MAX OF 1.0 SO THAT NO UP-REGULATION OCCURS

FIND THE SMOOTHED AVERAGE OF THREE PHOTOSYNTHETIC RATES JC, JE, AND JS USING COLLATZ'S
TWO QUADRATIC EQUATIONS, OR FIND THE MIN. OF THIS TWO RATES OR FIND MIN. OF JC AND JE.

DOWN-REGULATE PHOTOSYNTHESIS FOR C3 PLANTS

ESTIMATE LEAF MAINTENANCE RESPIRATION RATES AND NET PHOTOSYNTHETIC RATE. THIS NET P-
HOSYNTHETIC RATE IS /M^2 OF VEGETATED LAND.

RECENT STUDIES SHOW R_{mL} IS LESS TEMPERATURE SENSITIVE THAN PHOTOSYNTHESIS DURING DAY,

THAT'S WHY A SMALL Q10 VALUE IS USED DURING DAY.

FIND CO_2 CONCENTRATION AT LEAF SURFACE FOR ALL VEGETATION TYPES. ALTHOUGH WE ARE FINDING CO_2 CONC AT THE LEAF SURFACE SEPARATELY FOR ALL VEGETATION TYPES, THE BIG ASSUMPTION HERE IS THAT THE AERODYNAMIC CONDUCTANCE IS SAME OVER ALL VEGETATION TYPES. CLASS FINDS AERODYNAMIC RESISTANCE OVER ALL THE 4 SUB-AREAS, BUT NOT FOR DIFFERENT VEGETATION TYPES WITHIN A SUB-AREA. ALSO CHANGE AERODYNAMIC CONDUCTANCE, CFLUX, FROM M/S TO $MOL/M^2/S$

FIND STOMATAL CONDUCTANCE AS PER BALL-WOODROW-BERRY FORMULATION USED BY COLLATZ ET AL. OR USE THE LEUNING TYPE FORMULATION WHICH USES VPD INSTEAD OF RH

IF LIGHT IS TOO LESS MAKE PARAMETER BB VERY SMALL

FIND THE INTERCELLULAR CO_2 CONCENTRATION BASED ON ESTIMATED VALUE OF GC

SEE IF WE HAVE PERFORMED THE REQUIRED NO. OF ITERATIONS, IF NOT THEN WE GO BACK AND DO ANOTHER ITERATION

WHEN REQUIRED NO. OF ITERATIONS HAVE BEEN PERFORMED THEN FIND STOMATAL CONDUCTANCES FOR ALL VEGETATION TYPES IN M/S AND THEN USE CONDUCTANCES TO FIND RESISTANCES. GCTU IMPLIES GC IN TRADITIONAL UNITS OF M/S

DON'T WANT TO REDUCE RESISTANCE AT NIGHT TO LESS THAN OUR MAX. VALUE OF AROUND 5000 S/M

IF USING STORAGE LAI THEN WE SET STOMATAL RESISTANCE TO ITS MAXIMUM VALUE.

AND FINALLY TAKE WEIGHTED AVERAGE OF RC_VEG BASED ON FRACTIONAL COVERAGE OF OUR 4 VEGETATION TYPES

CONVERT AN_VEG AND RML_VEG TO $\mu\text{-MOL CO}_2/\text{M}^2.\text{SEC}$

6.52 src/read_from_job_options.f90 File Reference

Module for parsing command line arguments to program and reading joboptions files.

Functions/Subroutines

- subroutine, public **readjobopts::read_from_job_options**
- subroutine, public **readjobopts::parsecoords** (coordstring, val)

6.52.1 Detailed Description

Module for parsing command line arguments to program and reading joboptions files.

6.53 src/SCREENRH.f File Reference

CALCULATES SCREEN RELATIVE HUMIDITY BASED ON INPUT SCREEN TEMPERATURE, SCREEN SPECIFIC HUMIDITY AND SURFACE PRESSURE. THE FORMULAE USED HERE ARE CONSISTENT WITH THAT USED ELSEWHERE IN THE GCM PHYSICS.

Functions/Subroutines

Purpose: Address infiltration of rain and meltwater into snow pack, and snow ripening.

Functions/Subroutines

- subroutine [sninfl](#) (R, TR, ZSNOW, TSNOW, RHOSNO, HCPSNO, WSNOW, HTCS, HMFN, PCPG, ROFN, FI, ILG, IL1, IL2, JL)

6.55.1 Detailed Description

Purpose: Address infiltration of rain and meltwater into snow pack, and snow ripening.

6.55.2 Function/Subroutine Documentation

6.55.2.1 subroutine [sninfl](#) (real, dimension (ilg) *R*, real, dimension (ilg) *TR*, real, dimension (ilg) *ZSNOW*, real, dimension (ilg) *TSNOW*, real, dimension (ilg) *RHOSNO*, real, dimension (ilg) *HCPSNO*, real, dimension (ilg) *WSNOW*, real, dimension (ilg) *HTCS*, real, dimension (ilg) *HMFN*, real, dimension (ilg) *PCPG*, real, dimension (ilg) *ROFN*, real, dimension (ilg) *FI*, integer *ILG*, integer *IL1*, integer *IL2*, integer *JL*)

Parameters

<i>r</i>	Rainfall rate incident on snow pack [$m s^{-1}$]
<i>tr</i>	Temperature of rainfall [C]
<i>zsnow</i>	Depth of snow pack [m](z_g)
<i>tsnow</i>	Temperature of the snow pack [C](T_s)
<i>rhosno</i>	Density of snow pack [$kg m^{-3}$](ρ_s)
<i>hcpsno</i>	Heat capacity of snow pack [$J m^{-3} K^{-1}$](C_s)
<i>wsnow</i>	Liquid water content of snow pack [$kg m^{-2}$](w_s)
<i>htcs</i>	Internal energy change of snow pack due to conduction and/or change in mass [$W m^{-2}$](I_s)
<i>hmf</i>	Energy associated with freezing or thawing of water in the snow pack [$W m^{-2}$]
<i>pcpg</i>	Precipitation incident on ground [$kg m^{-2} s^{-1}$]
<i>rofn</i>	Runoff reaching the ground surface from the bottom of the snow pack [$kg m^{-2} s^{-1}$]
<i>fi</i>	Fractional coverage of subarea in question on modelled area $\square(X_i)$

The rainfall rate, i.e. the liquid water precipitation rate incident on the snow pack from the atmosphere, from canopy drip and/or from melting of the top of the snow pack, may cause warming and/or melting of the snow pack as a whole. The overall change of internal energy of the snow pack as a result of the rainfall added to it, I_s or HTCS, is calculated as the difference in I_s between the beginning and end of the subroutine:

$$\Delta I_s = X_i \Delta [C_s z_s T_s] / \Delta t$$

where C_s represents the volumetric heat capacity of the snow pack, T_s its temperature, Δ the length of the time step, and X_i the fractional coverage of the subarea under consideration relative to the modelled area.

Four diagnostic variables are evaluated at the outset. HRCOOL, the energy sink required to cool the whole rainfall amount to 0 C, is calculated from the rainfall rate and temperature, and the heat capacity of water. HRFREZ, the energy sink required to freeze all the rainfall, is obtained from the latent heat of melting, the density of water and the rainfall rate. HSNWRM, the energy required to warm the whole snow pack to 0 C, is calculated from the temperature, heat capacity and depth of the snow pack. HSNMLT, the energy required to melt all the snow, is obtained from the latent heat of melting and the heat capacity and depth of the snow pack.

If $\text{HRCOOL} \geq (\text{HSNWRM} + \text{HSNMLT})$, the energy contributed by the temperature of the rainfall is sufficient to warm to 0 C and melt the whole snow pack. HRCOOL is recalculated as the difference between HRCOOL and $(\text{HSNWRM} + \text{HSNMLT})$, and the snow depth is converted to a water depth ZMELT . The energy used to melt the snow is added to the diagnostic variables HMFN , representing the energy associated with water phase changes in the snow pack, and HTCS . The new temperature of the rainfall is calculated by applying HRCOOL over the new rainfall rate reaching the soil, which now includes the original rainfall rate, the melted snow pack and the liquid water that was contained in the snow pack. The depth, temperature, density, heat capacity and liquid water content of the snow pack are set to zero.

If $\text{HRCOOL} \geq \text{HSNWRM}$ but $\text{HRCOOL} < (\text{HSNWRM} + \text{HSNMLT})$, the energy contributed by the temperature of the rainfall is sufficient to warm the whole snowpack to 0 C but not to melt all of it. HSNMLT is therefore recalculated as $\text{HRCOOL} - \text{HSNWRM}$, and used to determine a melted depth of the snowpack ZMELT , which is subtracted from the snow depth ZSNOW . The energy used to melt this depth of snow is added to HMFN and HTCS . The total water now available for retention in the snowpack, WAVAIL , is obtained as the sum of the mass of melted water and the mass of water originally retained in the snow pack, WSNOW . This amount is compared to the water retention capacity of the snow pack, calculated from the maximum retention percentage by weight, WSNCAP (currently set to 4%). If WAVAIL is greater than the water retention capacity, WSNOW is set to the capacity value and the excess is reassigned to ZMELT . Otherwise WSNOW is set to WAVAIL and ZMELT is set to zero. The temperature of the snow and the temperature TR of the rainfall reaching the ground surface are each set to 0 C, HCPSNO is recalculated, and ZMELT is added to the rainfall rate R .

If $\text{HSNWRM} \geq (\text{HRCOOL} + \text{HRFREQ})$, the energy sink of the snow pack is sufficient to cool to 0 C and freeze all of the rainfall. HSNWRM is recalculated as the difference between HSNWRM and $(\text{HRCOOL} + \text{HRFREQ})$. The energy used in the freezing, HRFREQ , is added to HMFN and HTCS . The rainfall is applied to increasing the density of the snow pack RHOSNO ; if the new density is greater than the density of ice, RHOSNO is reset to the ice density and ZSNOW is recalculated. HCPSNO is also recalculated, and the new snow temperature is obtained from HSNWRM , HCPSNO and ZSNOW . R and TR are set to zero.

If $\text{HSNWRM} > \text{HRCOOL}$ and $\text{HSNWRM} < (\text{HRCOOL} + \text{HRFREQ})$, the energy sink of the snow pack is sufficient to cool the rainfall to 0 C, but not to freeze all of it. HRFREQ is therefore recalculated as $\text{HSNWRM} - \text{HRCOOL}$, and used to determine a depth of rain to be frozen, ZFREQ . The energy used in the freezing is added to HMFN and HTCS . The frozen rainfall is applied to increasing the density of the snow pack as above; if the calculated density exceeds that of ice, RHOSNO and ZSNOW are recalculated. The water available for retention in the snow pack, WAVAIL , is obtained as the sum of the unfrozen rainfall and WSNOW , and compared to the water retention capacity of the snow pack. If WAVAIL is greater than the water retention capacity, WSNOW is set to the capacity value and WAVAIL is recalculated. Otherwise WSNOW is set to WAVAIL and WAVAIL is set to zero. The heat capacity of the snow is recalculated, R is calculated from WAVAIL , and TR and TSNOW are set to zero.

Finally, the calculation of the change in internal energy is completed, and the rainfall rate leaving the bottom of the snow pack and reaching the soil is added to the diagnostic variables PCPG and ROFN .

6.56 src/SNOADD.f File Reference

Purpose: Add snow incident on the ground surface to the snow pack.

Functions/Subroutines

- subroutine [snoadd](#) (ALBSNO , TSNOW , RHOSNO , ZSNOW , HCPSNO , HTCS , FI , S , TS , RHOSNI , WSNOW , ILG , IL1 , IL2 , JL)

6.56.1 Detailed Description

Purpose: Add snow incident on the ground surface to the snow pack.

6.56.2 Function/Subroutine Documentation

6.56.2.1 subroutine snoadd (real, dimension(ilg) *ALBSNO*, real, dimension (ilg) *TSNOW*, real, dimension(ilg) *RHOSNO*, real, dimension (ilg) *ZSNOW*, real, dimension(ilg) *HCPSNO*, real, dimension (ilg) *HTCS*, real, dimension (ilg) *FI*, real, dimension (ilg) *S*, real, dimension (ilg) *TS*, real, dimension(ilg) *RHOSNI*, real, dimension (ilg) *WSNOW*, integer *ILG*, integer *IL1*, integer *IL2*, integer *JL*)

Parameters

<i>albsno</i>	Albedo of snow []
<i>tsnow</i>	Temperature of the snow pack [C](T_s)
<i>rhosno</i>	Density of snow pack [kgm^{-3}](ρ_s)
<i>zsnow</i>	Depth of snow pack [m](z_s)
<i>hcpsno</i>	Heat capacity of snow pack [$Jm^{-3}K^{-1}$](C_s)
<i>htcs</i>	Internal energy change of snow pack due to conduction and/or change in mass [Wm^{-2}](I_s)
<i>fi</i>	Fractional coverage of subarea in question on modelled area [](X_i)
<i>s</i>	Snowfall rate incident on snow pack [ms^{-1}]
<i>ts</i>	Temperature of snowfall [C]
<i>rhosni</i>	Density of fresh snow [kgm^{-3}]
<i>wsnow</i>	Liquid water content of snow pack [kgm^{-2}](w_s)

The change of internal energy HTCS of the snow pack as a result of the snowfall added to it is calculated as the difference in I_s between the beginning and end of the subroutine:

$$\Delta I_s = X_i \Delta [C_s z_s T_s] / \Delta t$$

where C_s represents the volumetric heat capacity of the snow pack, T_s its temperature, Δ the length of the time step, and X_i the fractional coverage of the subarea under consideration relative to the modelled area.

The amount of snow incident at the given time step, SNOFAL, is calculated from S and the timestep length DELT. If $SNOFAL \geq 0.1$ mm, the snow albedo is set to the fresh snow value of 0.84. Otherwise, if the snow is falling on bare ground, its initial albedo is set to the old snow value of 0.50. The heat capacity of the precipitating snow, HCPSNP, is calculated from the fresh snow density RHOSNI and the heat capacity and density of ice. The new temperature of the snow pack is calculated as a weighted average of its old temperature, weighted by the snow depth ZSNOW and heat capacity HCPSNO, and the snowfall temperature, weighted by SNOFAL and HCPSNP. The new density of snow is calculated as a weighted average of the original density RHOSNO and RHOSNI, and the new snow depth is calculated as $ZSNOW + SNOFAL$. Finally, the new heat capacity of the snow pack is obtained from the heat capacities of ice and water C_i and C_w , the snow, ice and water densities ρ_s , ρ_{ho_i} , and ρ_w , and the water content and depth of the snow pack w_s and z_s , as:

$$C_s = C_i [\rho_s / \rho_i] + C_w w_s / [\rho_w z_s]$$

6.57 src/SNOALBA.f File Reference

Purpose: Diagnose snowpack visible and near-IR albedos given the all-wave albedo at the current time step. Calculate snowpack transmissivity for shortwave radiation.

Functions/Subroutines

- subroutine [snoalba](#) (ALVSSN, ALIRSN, ALVSSC, ALIRSC, ALBSNO, TRSNOWC, ALSNO, TRSNOWG, F←SDB, FSFB, RHOSNO, REFSN, BCSN, SNO, CSZ, ZSNOW, FSNO, ASVDAT, ASIDAT, ALVSG, ALIRG, ILG, IG, IL1, IL2, JL, IALS, NBS, ISNOALB)

6.57.1 Detailed Description

Purpose: Diagnose snowpack visible and near-IR albedos given the all-wave albedo at the current time step. Calculate snowpack transmissivity for shortwave radiation.

6.57.2 Function/Subroutine Documentation

6.57.2.1 subroutine snoalba (real, dimension(ilg) *ALVSSN*, real, dimension(ilg) *ALIRSN*, real, dimension(ilg) *ALVSSC*, real, dimension(ilg) *ALIRSC*, real, dimension(ilg) *ALBSNO*, real, dimension(ilg) *TRSNOWC*, real, dimension (ilg,nbs) *ALSNO*, real, dimension(ilg,nbs) *TRSNOWG*, real, dimension(ilg,nbs) *FSDB*, real, dimension(ilg,nbs) *FSFB*, real, dimension(ilg) *RHOSNO*, real, dimension (ilg) *REFSN*, real, dimension (ilg) *BCSN*, real, dimension (ilg) *SNO*, real, dimension (ilg) *CSZ*, real, dimension (ilg) *ZSNOW*, real, dimension (ilg) *FSNOW*, real, dimension(ilg) *ASVDAT*, real, dimension(ilg) *ASIDAT*, real, dimension (ilg) *ALVSG*, real, dimension (ilg) *ALIRG*, integer *ILG*, integer *IG*, integer *IL1*, integer *IL2*, integer *JL*, integer *IALS*, integer *NBS*, integer *ISNOALB*)

Parameters

<i>nbs</i>	Number of modelled shortwave radiation wavelength bands
<i>isnoalb</i>	Switch to model snow albedo in two or more wavelength bands
<i>alvssn</i>	Visible albedo of snow pack on bare ground $[(\alpha_{s,VIS})]$
<i>alirsn</i>	Near-IR albedo of snow pack on bare ground $[(\alpha_{s,NIR})]$
<i>alvssc</i>	Visible albedo of snow on ground under vegetation canopy []
<i>alirsc</i>	Near-IR albedo of snow on ground under vegetation canopy []
<i>trsnowc</i>	Transmissivity of snow under vegetation to shortwave radiation $[(\tau_{s,c})]$
<i>alsno</i>	Albedo of snow in each modelled wavelength band []
<i>trsnowg</i>	Transmissivity of snow in bare areas to shortwave radiation $[(\tau_{s,g})]$
<i>alvsg</i>	Near-IR albedo f bare ground []
<i>alirg</i>	Visible albedo of bare ground []
<i>fsdb</i>	Direct solar radiation in each modelled wavelength band $[Wm^{-2}]$
<i>fsfb</i>	Diffuse solar radiation in each modelled wavelength band $[Wm^{-2}]$
<i>albsno</i>	All-wave albedo of snow pack $[(\alpha_{s,T})]$
<i>zsnow</i>	Depth of snow $[m](z_s)$
<i>fsnow</i>	Fractional coverage of snow on grid cell []
<i>asvdat</i>	Assigned value of visible albedo of snow pack – optional []
<i>asidat</i>	Assigned value of near-IR albedo of snow pack – optional []
<i>refsn</i>	Snow grain size [m]
<i>bcsn</i>	Black carbon mixing ratio $[kgm^{-3}]$
<i>csz</i>	Cosine of solar zenith angle []
<i>sno</i>	Mass of snow pack $[kgm^{-2}]$
<i>rhosno</i>	Density of snow pack $[kgm^{-3}]$

In subroutine SNOALBW, called at the end of CLASSW, the change of total snow albedo over the current time step is calculated using an empirical exponential decay function, which has different coefficients depending on whether the snow is dry or melting. In this subroutine, the visible and near-IR components of the snow albedo are diagnosed from the total albedo. According to the literature (Aguado, 1985 **[Aguado1985-fv]** ; Robinson and Kukla, 1984; Dirmhirn and Eaton, 1975 **[Dirmhirn1975-vx]**), the following represent typical snow albedos for fresh snow, old dry snow and melting snow:

	Total albedo	Visible albedo	Near-IR albedo
Fresh snow	0.84	0.95	0.73
Old dry snow	0.70	0.84	0.56
Melting snow	0.50	0.62	0.38

The same decay function is assumed to apply to all three albedo ranges, so the relative location of the visible and near-IR albedos, $\alpha_{s,VIS}$ and $\alpha_{s,NIR}$, on the decay curve will be analogous to that of the total albedo, $\alpha_{s,T}$. Thus, for dry snow:

$$[\alpha_{s,VIS} - 0.84] / [0.95 - 0.84] = [\alpha_{s,T} - 0.70] / [0.84 - 0.70] [\alpha_{s,NIR} - 0.56] / [0.73 - 0.56] = [\alpha_{s,T} - 0.70] / [0.84 - 0.70]$$

or, simplifying:

$$\alpha_{s,VIS} = 0.7857\alpha_{s,T} + 0.2900\alpha_{s,NIR} = 1.2142\alpha_{s,T} - 0.2900$$

For melting snow:

$$[\alpha_{s,VIS} - 0.62] / [0.95 - 0.62] = [\alpha_{s,T} - 0.50] / [0.84 - 0.50] [\alpha_{s,NIR} - 0.38] / [0.73 - 0.38] = [\alpha_{s,T} - 0.50] / [0.84 - 0.50]$$

or, simplifying:

$$\alpha_{s,VIS} = 0.9706\alpha_{s,T} + 0.1347\alpha_{s,NIR} = 1.0294\alpha_{s,T} - 0.1347$$

The above calculations are performed if the flag IALS is set to zero. If IALS is set to one, indicating that assigned snow albedos are to be used instead of calculated values, $\alpha_{s,VIS}$ and $\alpha_{s,NIR}$ are set to the assigned values ASVDAT and ASIDAT respectively. The sub-canopy values of visible and near-IR albedo are currently set equal to the open snowpack values (this is expected to change if a canopy litterfall parametrization is developed).

The transmissivity of snow under vegetation $\tau_{s,c}$ is then calculated from the snow depth ZSNOW using Beer's

law, with an empirical extinction coefficient of $25.0m^{-1}$ derived from the literature (Grenfell and Maykut, 1977 [Grenfell1977-pi] ; Thomas, 1963):

$$\tau_{s,c} = \exp[-25.0z_s]$$

If the ISNOALB switch is set to zero, the value of ALSNO in the first wavelength band is set to the previously calculated value of $\alpha_{s,VIS}$ and the values for the remaining bands are set to the previously calculated value of $\alpha_{s,NIR}$; the value of $\tau_{s,g}$ is set to $\tau_{s,c}$. If the ISNOALB switch is set to 1, a new parameterization for the snow albedo and transmissivity in four shortwave radiation bands (one visible and three near-IR) is used, according to Cole et al. (2017). This parameterization incorporates the effects of snow grain size and black carbon content, and makes use of lookup tables contained in the CCCma subroutines SNOW_ALBVAL and SNOW_TRANVAL.

Convert the units of the snow grain size and BC mixing ratio Snow grain size from meters to microns and BC from $kgBC/m^3$ to ng BC/kg SNOW

Purpose: Sublimation calculations for the snow pack on the ground.

Functions/Subroutines

- subroutine [snovap](#) (RHOSNO, ZSNOW, HCPSNO, TSNOW, EVAP, QFN, QFG, HTCS, WLOST, TRUNOF, RUNOFF, TOVRFL, OVRFLW, FI, R, S, RHOSNI, WSNOW, ILG, IL1, IL2, JL)

6.58.1 Detailed Description

Purpose: Sublimation calculations for the snow pack on the ground.

6.58.2 Function/Subroutine Documentation

6.58.2.1 subroutine [snovap](#) (real, dimension(ilg) *RHOSNO*, real, dimension (ilg) *ZSNOW*, real, dimension(ilg) *HCPSNO*, real, dimension (ilg) *TSNOW*, real, dimension (ilg) *EVAP*, real, dimension (ilg) *QFN*, real, dimension (ilg) *QFG*, real, dimension (ilg) *HTCS*, real, dimension (ilg) *WLOST*, real, dimension(ilg) *TRUNOF*, real, dimension(ilg) *RUNOFF*, real, dimension(ilg) *TOVRFL*, real, dimension(ilg) *OVRFLW*, real, dimension (ilg) *FI*, real, dimension (ilg) *R*, real, dimension (ilg) *S*, real, dimension(ilg) *RHOSNI*, real, dimension (ilg) *WSNOW*, integer *ILG*, integer *IL1*, integer *IL2*, integer *JL*)

Parameters

<i>rhosno</i>	Density of snow pack [kgm^{-3}](ρ_s)
<i>zsnow</i>	Depth of snow pack [m](z_g)
<i>hcpsno</i>	Heat capacity of snow pack [$Jm^{-3}K^{-1}$](C_s)
<i>tsnow</i>	Temperature of the snow pack [C](T_s)
<i>evap</i>	Sublimation rate from snow surface at start of subroutine [ms^{-1}]
<i>qfn</i>	Sublimation from snow pack [$kgm^{-2}s^{-1}$]
<i>qfg</i>	Evaporation from ground [$kgm^{-2}s^{-1}$]
<i>htcs</i>	Internal energy change of snow pack due to conduction and/or change in mass [Wm^{-2}](I_s)
<i>wlost</i>	Residual amount of water that cannot be supplied by surface stores [kgm^{-2}]
<i>trunof</i>	Temperature of total runoff [K]
<i>runoff</i>	Total runoff [ms^{-1}]

<i>tovrfl</i>	Temperature of overland flow [K]
<i>ovrflw</i>	Overland flow from top of soil column [ms^{-1}]
<i>fi</i>	Fractional coverage of subarea in question on modelled area $\square(X_i)$
<i>r</i>	Rainfall rate incident on snow pack [ms^{-1}]
<i>s</i>	Snowfall rate incident on snow pack [$kgm^{-2}s^{-1}$]
<i>rhosni</i>	Density of fresh snow [kgm^{-3}]
<i>wsnow</i>	Liquid water content of snow pack [kgm^{-2}](w_s)

These calculations are done if a snowpack is present and there is no rainfall or snowfall occurring. The change of internal energy I_s of the snow pack as a result of the change in its mass is calculated as the difference in I_s between the beginning and end of the subroutine:

$$\Delta I_s = X_i \Delta [C_s z_s T_s] / \Delta t$$

where C_s represents the volumetric heat capacity of the snow pack, T_s its temperature, Δt the length of the time step, and X_i the fractional coverage of the subarea under consideration relative to the modelled area.

If the sublimation rate EVAP over the snow pack is negative (downward), the deposited depth of snow ZADD is calculated from EVAP by converting it from a liquid water flux to a fresh snow depth using RHOSNI, the fresh snow density. The snowpack density is updated as a weighted average of the original snow density RHOSNO and RHOSNI. The new snow depth is calculated as the sum of the old snow depth ZSNOW and ZADD. The new volumetric heat capacity of the snow pack is obtained from the heat capacities of ice and water C_i and C_w , the snow, ice and water densities ρ_s , ρ_i , and ρ_w , and the water content and depth of the snow pack w_s and z_s , as:

$$C_s = C_i [\rho_s / \rho_i] + C_w w_s / [\rho_w z_s]$$

If the sublimation rate is positive, the depth of the snow pack ZLOST that is sublimated over the time step is calculated from EVAP using RHOSNO. If $ZLOST \leq ZSNOW$, the snow depth is reduced and HCPSNO is recalculated. Otherwise the deficit amount ZREM is calculated from $ZLOST - ZSNOW$ and converted to a depth of water. This amount is further converted to an evaporation rate by applying a correction factor of $(L_m + L_v) / L_v$, where L_m is the latent heat of melting and L_v is the latent heat of vaporization (to account for the fact that the energy is now being used to evaporate water instead of sublimate snow). This necessarily leads to a small discrepancy between the overall vapour flux for the subarea that was originally calculated in CLASST, and the actual change of water storage in the subarea, and therefore this discrepancy is added to the housekeeping variable WLOST for use in the water balance checks done later in CHKWAT. If there was liquid water in the snow pack, WSNOW, it is assigned to overall runoff RUNOFF, and to overland flow OVRFLW. The resulting temperatures of the runoff and overland flow, TRUNOF and TOVRFL, are recalculated as weighted averages using the original runoff amounts and temperatures, and the original snow temperature TSNOW for WSNOW. The snow depth, heat capacity, temperature and water content are all set to zero. Finally, since ZREM now becomes soil evaporation rather than snow sublimation, the diagnostic variables QFN and QFG, representing the vapour flux from snow and soil respectively, are adjusted to reflect this.

6.59.1 Detailed Description

Canadian Terrestrial Ecosystem Model (CTEM) Soil Methane Oxidation Subroutine.

Coded up based on [Curry2007-du].

6.59.2 Function/Subroutine Documentation

6.59.2.1 subroutine soil_ch4uptake (integer, intent(in) *IL1*, integer, intent(in) *IL2*, real, dimension(ilg,ignd), intent(in) *tbar*, real, dimension(ilg,ignd), intent(in) *THP*, real, dimension(ilg,ignd), intent(in) *BI*, real, dimension(ilg,ignd), intent(in) *THLQ*, real, dimension(ilg,ignd), intent(in) *THIC*, real, dimension(ilg,ignd), intent(in) *PSIS*, real, intent(in) *GRAV*, real, dimension(ilg,ican), intent(in) *FCAN*, logical, intent(in) *obswetf*, real, dimension(ilg), intent(in) *wetfdyn*, real, dimension(nlat), intent(in) *wetfracgrd*, integer, dimension(ilg,ignd), intent(in) *isand*, real, intent(in) *RHOW*, real, intent(in) *RHOICE*, real, dimension(ilg), intent(in) *atm_CH4*, real, dimension(ilg), intent(out) *CH4_soills*)

Parameters

in	<i>tbar</i>	Temperature of soil layers (K) - daily average
in	<i>thp</i>	Total porosity ($cm^3 cm^{-3}$) - daily average
in	<i>bi</i>	Clapp and Hornberger b-term (-)
in	<i>thlq</i>	Fractional water content (-) - daily average
in	<i>thic</i>	Fractional ice content (-) - daily average
in	<i>psis</i>	Soil moisture suction at saturation (m)
in	<i>fcan</i>	Fractional coverage of vegetation (-)
in	<i>wetfracgrd</i>	Prescribed fraction of wetlands in a grid cell
in	<i>wetfdyn</i>	Dynamic gridcell wetland fraction determined using slope and soil moisture
in	<i>atm_ch4</i>	Atmospheric CH_4 concentration at the soil surface (ppmv)
in	<i>grav</i>	Acceleration due to gravity (ms^{-1})
in	<i>obswetf</i>	Switch, if true then use the prescribed wetland cover
in	<i>rhow</i>	Density of water (kgm^{-3})
in	<i>rhoice</i>	Density of ice (kgm^{-3})
in	<i>isand</i>	flag for soil/bedrock/ice/glacier
out	<i>ch4_soills</i>	Methane uptake into the soil column ($mgCH_4m^{-2}s^{-1}$)

Begin

The soil oxidation methane sink is assumed to only operate in the first model soil layer, thus we only consider that layer here.

not soil so move on.

Convert tbar to Tsoil (from K to deg C)

Find the diffusion coefficient in soil (D_soil)

First the temperature factor, G_T:

Find the air filled porosity, THP_air:

Note: THP_air can fall to < 0 after snow melt

The BI (Clapp and Hornberger b-term) is already calculated by CLASS as: $BI = 15.9 * f_{clay} + 2.91$, thus we use that value.

G_soil is the influence of the soil texture, moisture, and porosity:

The diffusion coefficient of CH4 in soil is then:

Determine the first-order oxidation rate constant (k_oxidr)

First find the temperature term, r_T (FLAG note that Charles' original code does not have the high temp limit!)

all other temps (<-10 and >=43.3)

Next find the term based on soil moisture (suction)

Find the soil water potential for the uppermost layer need the absolute value.

Convert units from m to kPa

0.2 MPa in paper (NOTE: In Charles's code this is \leq , but is < in paper)

0.2 and 100 MPa in paper

$\text{psi} > 100 \text{ MPa}$.

Find the flux correction for croplands

Find the flux correction due to wetlands

Use the prescribed wetland fractions

use the dynamically determined wetland area

Find the surface flux ($\text{CH}_4_{\text{soils}}$) for each tile, then for each gridcell

Convert from $\text{mg CH}_4 \text{ m}^{-2} \text{ s}^{-1}$ to $\text{umol CH}_4 \text{ m}^{-2} \text{ s}^{-1}$

Parameters

<i>r</i>	Rainfall rate incident on ground [ms^{-1}]
----------	---

<i>tr</i>	Temperature of rainfall [C]
<i>s</i>	Snowfall rate incident on ground [ms^{-1}]
<i>ts</i>	Temperature of snowfall [C]
<i>rhosni</i>	Density of fresh snow [kgm^{-3}]
<i>evapg</i>	Evaporation rate from surface [ms^{-1}]
<i>qfn</i>	Sublimation from snow pack [$kgm^{-2}s^{-1}$]
<i>qfg</i>	Evaporation from ground [$kgm^{-2}s^{-1}$]
<i>pcpn</i>	Precipitation incident on ground [$kgm^{-2}s^{-1}$]
<i>pcpg</i>	Precipitation incident on ground [$kgm^{-2}s^{-1}$]
<i>fi</i>	Fractional coverage of subarea in question on modelled area []

This subroutine starts with the precipitation rate under the canopy (a result of throughfall and unloading) and calculates the resulting overall evaporation or deposition rates.

For IWATER = 2 (snow on the ground under the canopy), the water vapour flux EVAPG at the ground surface is in the first instance assumed to be sublimation. Thus the first step is to compare it to the snowfall rate. The sum of the snowfall rate and the evaporation rate, SADD, is calculated as $S - EVAPG$, with EVAPG converted from a liquid water flux (the standard output from TSOLVC) to a snow flux. If SADD is greater than zero (indicating a downward flux) the snowfall rate is set to SADD and EVAPG is set to zero. Otherwise EVAPG is set to -SADD (converted back to a liquid water flux), and S and TS are set to zero.

After this section, any remaining evaporative flux is compared to the rainfall rate. The sum RADD is calculated as $R - EVAPG$. If RADD is greater than zero, the rainfall rate is set to RADD and EVAPG is set to zero. Otherwise EVAPG is set to -RADD, and R and TR are set to zero.

Analogous calculations are done for IWATER = 1 (bare ground under the canopy). In this case EVAPG is assumed in the first instance to be evaporation or condensation. Thus the first step is to compare it to the rainfall rate, and the same steps are followed as in the paragraph above. Afterwards, any remaining vapour flux is compared to the snowfall rate. If SADD is positive (downward), EVAPG, which is now considered to be absorbed into the snowfall rate, is subtracted from the ground vapour flux QFG and added to the snow vapour flux QFN. If SADD is negative (upward), S, which has now been absorbed into the evaporative flux, is subtracted from the snow precipitation flux PCPN and added to the ground precipitation flux PCPG.

<i>hmfq</i>	Energy associated with phase change of water in soil layers [<i>Wm</i> ⁻²]
<i>htc</i>	Internal energy change of soil layer due to conduction and/or change in mass [<i>Wm</i> ⁻²] (<i>I_g</i>)
<i>fi</i>	Fractional coverage of subarea in question on modelled area [](<i>X_i</i>)
<i>qfrez</i>	Energy sink for freezing of water at the ground surface [<i>Wm</i> ⁻²]
<i>wsnow</i>	Liquid water content of snow pack [<i>kgm</i> ⁻²](<i>w_s</i>)
<i>ta</i>	Air temperature [<i>K</i>]
<i>tbar</i>	Temperature of soil layer [<i>C</i>](<i>T_g</i>)
<i>isand</i>	Sand content flag

Freezing of water ponded on the ground surface occurs if an energy sink QFREQ is produced as a result of the solution of the surface energy balance, or if the pond temperature at the beginning of the subroutine has been projected to be below 0 C. The change of internal energy *I* in the snow and first soil layer (which for the purposes of diagnostic calculations includes the ponded water) as a result of these processes is calculated as the difference in *I* between the beginning and end of the subroutine:

$$\Delta I_s = X_i \Delta(C_s T_s z_s) / \Delta t \quad \Delta I_g = X_i \Delta(C_w T_p z_p) / \Delta t$$

where the *C* terms represent volumetric heat capacities, the *T* terms temperatures, and the *z* terms depths of the snow pack and the ponded water respectively, Δt is the length of the time step, and *X_i* the fractional coverage of the subarea under consideration relative to the modelled area.

The energy sink HADD to be applied to the ponded water is calculated from QFREQ and the pond temperature *T_p* (if it is below 0 C). Two diagnostic variables, HCOOL and HCONV, are calculated as the energy sink required to cool the ponded water to 0 C, and that required both to cool and to freeze the ponded water, respectively. If $HADD \leq HCOOL$, the available energy sink is only sufficient to decrease the temperature of the ponded water. This decrease is applied, and the energy used is added to the internal energy HTC of the first soil layer.

If $HADD > HCOOL$ but $HADD \leq HCONV$, the available energy sink is sufficient to decrease the ponded water temperature to 0 C and to freeze part of it. The energy used in freezing is calculated as $HADD - HCOOL$, and is used to calculate the depth of frozen water ZFREQ, which is then subtracted from the ponded water depth ZPOND. HCOOL is added to HTC, and ZFREQ is converted from a depth of water to a depth of ice and added to the snow pack. If there is not a pre-existing snow pack, the snow albedo is set to the background value for old snow, 0.50. The temperature, density and heat capacity of the snow pack are recalculated.

If $HADD > HCONV$, the available energy sink is sufficient to cool and freeze the whole depth of ponded water, and also to decrease the temperature of the ice thus formed. The ponded water depth is converted to a depth of ice ZFREQ, and HCOOL is added to HTC. In order to avoid unphysical temperature decreases caused by the length of the time step and the small ponding depth, a limit is set on the allowable decrease. The theoretical temperature of the newly formed ice, TTEST, is calculated from $HADD - HCONV$. If there is a pre-existing snow pack, the limiting temperature TLIM is set to the minimum of the snow pack temperature TSNOW, the first soil layer temperature, and 0 C; otherwise it is set to the minimum of the air temperature, the first soil layer temperature and 0 C. If $TTEST < TLIM$, the new ice is assigned TLIM as its temperature in the recalculation of TSNOW, the excess heat sink $HEXCES$ is calculated from $HADD$ and $TLIM$ and assigned to the ground heat flux GZERO, and $HADD - HEXCES$ is used to update HTC. Otherwise the new ice is assigned TTEST as its temperature in the recalculation of TSNOW, and $HADD$ is used to update HTC. If there is not a pre-existing snow pack, the snow albedo is set to the background value. The density, depth and heat capacity of the snow pack are recalculated, and the pond depth and temperature are set to zero.

At the end of the subroutine, the internal energy calculations are completed, and ZFREQ is used to update the

diagnostic variable HMFG describing the energy associated with phase changes of water in soil layers, and also the diagnostic variables WTRS and WTRG describing transfers of water into or out of the snow and soil respectively. Finally, the initial step in the calculation of the internal energy change for the ponded water over the following subroutines GRINFL and GRDRAN is performed (the calculation is completed in subroutine TMCALC).

<i>ta</i>	Air temperature [K]
<i>wsnow</i>	Liquid water content of snow pack $[kgm^{-2}](w_s)$
<i>tctop</i>	Thermal conductivity of soil at top of soil layer $[Wm^{-1}K^{-1}]$
<i>tcbot</i>	Thermal conductivity of soil at bottom of soil layer $[Wm^{-1}K^{-1}]$
<i>zplim</i>	Limiting depth of ponded water [m]
<i>thpor</i>	Pore volume in soil layer $(\theta_p)[m^3m^{-3}]$
<i>thlmin</i>	Residual soil liquid water content remaining after freezing or evaporation $(\theta_r)[m^3m^{-3}]$
<i>hcps</i>	Heat capacity of soil material $[Jm^{-3}K^{-1}](C_m)$
<i>delzw</i>	Permeable thickness of soil layer $(\Delta z_{g,w})[m]$
<i>delzz</i>	Soil layer thicknesses to bottom of permeable depth for standard three-layer configuration, or to bottom of thermal depth for multiple layers $(\Delta z_{g,z})[m]$
<i>delz</i>	Overall thickness of soil layer [m]
<i>isand</i>	Sand content flag
<i>gflux</i>	Heat flow between soil layers $[Wm^{-2}]$

If a full-scale hydrological modelling application is not being run, that is, if only vertical fluxes of energy and moisture are being modelled, the flag IWF is pre-set to zero. In this case, overland flow of water is treated using a simple approach: if the ponded depth of water on the soil surface ZPOND exceeds a limiting value ZPLIM (which varies by land surface type), the excess is assigned to overland flow. These calculations are carried out in loop 100, for all modelled areas except ice sheets (which are handled in subroutine ICEBAL). The overall runoff from the modelled area in question, RUNOFF, is incremented by the excess ponded water, and the overland flow for the whole grid cell OVRFLW is incremented by the product of the excess ponded water and the fractional area of the grid cell. The temperature of the overall runoff from the modelled area TRUNOF, and the temperature of the overland flow for the grid cell TOVRFL, are calculated as weighted averages over their previous values and the ponded water temperature TPOND. Finally, ZPOND is set to ZPLIM.

In loop 200, the calculation of the change in internal energy HTC within the soil layers due to movement of soil water (addressed in the preceding subroutines GRINFL and GRDRAN) is completed. (The initial step was performed at the end of subroutine TWCALC.) The volumetric heat capacity of the soil layers HCP is recalculated as a weighted average over the volumetric contents of liquid water, frozen water and soil particles. The temperature TBAR of each soil layer is recalculated as a weighted average of the liquid water temperature TBARW resulting from soil water movement, and the previous soil layer temperature. As noted in the documentation for subroutine TWCALC, TBARW and HCP apply only over the permeable depth of the soil layer, DELZW, whereas TBAR applies over the whole depth, DELZZ, and is associated with HCPSND, the volumetric heat capacity assigned to rock, in the interval DELZZ- DELZW. (For the default three-layer version of CLASS, DELZZ=DELZW in the third soil layer; see the documentation of loop 550 below.)

In loop 300 the calculation of the change of internal energy within the first soil layer due to changes in the surface ponded water is completed (for diagnostic purposes, the first level of HTC includes the internal energy of both the ponded water and the first soil layer). (The initial step of this calculation was performed at the end of subroutine

TFREEZ.) The flow of heat between the bottom of the ponded water and the top of the first soil layer, GP1, is calculated by assuming a linear variation with depth of the heat flux between the top of the pond, GZERO, and between the first and second soil layers, G12. Since the heat flux $G(z)$ varies directly with the temperature gradient $dT(z)/dz$, it can be seen that this approach is consistent with the assumption made in the CLASST subroutines that $T(z)$ is a quadratic function of depth (and therefore that its first derivative is a linear function of depth). The temperature of the ponded water is stepped ahead using GZERO and GP1, and GZERO is reset to GP1 for use in the later soil temperature calculations.

In the 400 loop, a check is performed to ascertain whether the ponded water temperature has fallen below 0 C as a result of the above temperature change. If so, calculations are carried out analogous to those done in TFREEZ. A recalculation of the available energy in the snow pack, HTCS, is initiated. The available energy sink HADD is calculated from TPOND and ZPOND, and TPOND is set to 0 C. The amount of energy required to freeze the whole depth of ponded water is calculated as HCONV. An update of the first level value of HTC, reflecting the freezing of ponded water, is initiated. If $HADD < HCONV$, the available energy sink is sufficient to freeze only part of the ponded water. This depth ZFREEZ is calculated from HADD, and subtracted from ZPOND. ZFREEZ is then converted from a depth of water to a depth of ice, and is reassigned as part of the snow pack. The snow temperature, density, heat capacity and depth are recalculated as weighted averages of the pre-existing snow properties and those of the frozen water. If there was no snow on the ground to begin with, the snow albedo is initialized to its minimum background value of 0.50.

If $HADD > HCONV$, the available energy sink is sufficient to freeze the whole depth of ponded water and then to decrease the frozen water temperature to below 0 C. ZFREEZ is evaluated as ZPOND converted to a depth of ice, and the remaining energy sink $HADD - HCONV$ is used to calculate a test temperature TTEST of the newly formed ice. In order to avoid unphysical overshoots of the frozen water temperature, a limiting temperature TLIM is determined as the minimum of the snow temperature and the first level soil temperature if there is pre-existing snow, and as the minimum of the air temperature and the first level soil temperature if not. If $TTEST < TLIM$, the excess energy sink required to decrease the frozen water temperature from TLIM to TTEST is calculated and added to GZERO, and the new frozen water temperature is assigned as TLIM; otherwise it is assigned as TTEST. The energy sink used to cool the frozen water from 0 C to TLIM or TTEST is decremented from the first level of HTC, and the snow temperature is recalculated as the weighted average of the pre-existing snow temperature and the frozen water temperature. If there was no pre-existing snow, the snow albedo is initialized to the background value of 0.50. The density, heat capacity and depth of the snow are recalculated as above. Finally, the recalculations of the internal energy diagnostic variables HTC and HTCS are completed; and ZFREEZ is used to update the diagnostic variable HMFG describing the energy associated with phase changes of water in soil layers, and the diagnostic variables WTRS and WTRG describing transfers of water into or out of the snow and soil respectively.

In the 500, 550 and 600 loops, the heat fluxes between soil layers and the updated temperatures for the soil layers are calculated according to the discretization approach that has been selected for the model run. It is assumed that the first two layer thicknesses are always set to 0.10 and 0.25 m respectively, but two possible options exist for the treatment of deeper layers. In the operational, "three-layer" configuration, a single third soil layer is modelled of thickness 3.75 m, with a user-specified permeable thickness DELZW. TBAR of the third layer is taken to apply to this permeable thickness, whereas a separate bedrock temperature, TBASE, is carried for the impermeable thickness, represented by DELZ-DELZW. This strategy is adopted so that temperature variations caused by melting and freezing of water are confined to the permeable thickness. In the "multi-layer" configuration, there can be any number of deeper layers, of thicknesses specified by the user (with the proviso that the thicknesses not be small enough to lead to numerical instability in the forward explicit time-stepping scheme). In this configuration it is deemed unnecessary to carry a separate calculation of TBASE.

In the CLASST subroutines, the heat fluxes at the top of the first soil layer, and between the first and second and the second and third soil layers, were determined. In loop 500, the fluxes between the remaining soil layers are calculated for the multi-layer configuration, and assigned to the heat flux vector GFLUX. Since the temperature variation is increasingly damped with depth, a simple linearization of the temperature profile is used. The expression for the ground heat flux at depth z , $G(z)$, which depends on the thermal conductivity $\lambda(z)$ and the temperature gradient, is given as: $G(z) = \lambda(z)dT(z)/dz$. The linearized form is written as: $G_j = (\lambda_{j-1} + \lambda_j)(T_{j-1} - T_j)/(\Delta z_{j-1} - \Delta z_j)$ where G_j is the heat flux at the top of layer j , and λ_j , T_j and Δz_j refer to the thermal conductivity, temperature and heat capacity of the layer.

In the 550 loop, the first and second soil layer temperatures are stepped ahead using GZERO, G12 and G23. (Recall that the calculated heat capacity HCP applies to the permeable thickness DELZW, and the heat capacity of rock HCPSND applies to the rest of the layer thickness, DELZZ-DELZW.) If the three-layer configuration is being used, then a check is carried out to ascertain whether the permeable thickness DELZZ of the third layer is greater

than zero. If so, and if DELZZ is not effectively equal to DELZ, the heat flow G3B at the interface between the permeable thickness and the underlying bedrock is calculated using the linearized heat flow equation given above; TBAR is updated using the difference between G23 and G3B, and TBASE is updated using the difference between G3B and GGEO, the geothermal heat flux at the bottom of the soil profile. If DELZZ is equal to DELZ, the whole layer is permeable and TBAR is updated using the difference between G23 and GGEO. If DELZZ is zero, the whole layer is impermeable, and TBASE is updated using the difference between G23 and GGEO. HTC for the third layer is updated with the GGEO value. Finally, if the multi-layer configuration is being used, TBAR of the third layer is updated using G23, the flux at the top of the layer. For diagnostic purposes, the first three levels of the GFLUX vector are assigned as GZERO, G12 and G23 respectively.

In the 600 loop, the remaining soil layer temperature calculations are done for layers 3 and deeper, for the multi-layer configuration. At the beginning and end of the loop an updated calculation of HTC for the layer in question is initiated and completed respectively. For the third layer, TBAR is updated using the heat flux at the bottom of the layer; for the last layer, TBAR is updated using the difference between GFLUX at the top of the layer and GGEO at the bottom. For the intermediate layers, TBAR is calculated using the difference between the GFLUX values at the top and bottom of the layer.

In the 700 loop, checks are carried out to determine whether, as a result of the forward stepping of the temperature, TBAR has fallen below 0 C while liquid water still exists in the layer, or risen above 0 C while frozen water still exists in the layer. If either occurs, adjustments to the water content are performed analogous to those done in subroutine TWCALC. Again, at the beginning and end of the loop an updated calculation of HTC for each layer in turn is initiated and completed respectively.

If the soil layer temperature is less than 0 C and the volumetric liquid water content THLIQ of the layer is greater than the residual water content THLMIN, the water content THFREZ that can be frozen by the available energy sink is calculated from TBAR and the weighted average of HCP and HCPSND. If $\text{THFREZ} \leq \text{THLIQ} - \text{THLMIN}$, all of the available energy sink is used to freeze part of the liquid water content in the permeable part of the soil layer. The amount of energy involved is subtracted from HTC and added to HMFG. THFREZ is subtracted from THLIQ, converted to an ice volume and added to THICE. HCP is recalculated, and the layer temperature is set to 0 C. Otherwise, all of the liquid water content of the layer above THLMIN is converted to frozen water, and HMFG and HTC are recalculated to reflect this. HCP is recomputed, and the remaining energy sink HADD is applied to decreasing the temperature of the soil layer.

If the soil layer temperature is greater than 0 C and the volumetric ice content THICE of the layer is greater than zero, the ice content THMELT that can be melted by the available energy is calculated from TBAR and the weighted average of HCP and HCPSND. If $\text{THMELT} \leq \text{THICE}$, all of the available energy is used to melt part of the frozen water content of the permeable part of the layer. The amount of energy involved is subtracted from HTC and added to HMFG. THMELT is subtracted from THICE, converted to a liquid water volume and added to THLIQ; HCP is recalculated and the layer temperature is set to 0 C. Otherwise, all of the frozen water content of the layer is converted to liquid water, and HMFG and HTC are recalculated to reflect this. HCP is recomputed, and the remaining energy HADD is applied to increasing the temperature of the soil layer.

Purpose: Address melting of the snow pack.

Functions/Subroutines

- subroutine [tmelt](#) (ZSNOW, TSNOW, QMELT, R, TR, GZERO, RALB, HMFN, HTCS, HTC, FI, HCPSNO, R←HOSNO, WSNOW, ISAND, IG, ILG, IL1, IL2, JL)

6.64.1 Detailed Description

Purpose: Address melting of the snow pack.

6.64.2 Function/Subroutine Documentation

6.64.2.1 subroutine tmelt (real, dimension (ilg) *ZSNOW*, real, dimension (ilg) *TSNOW*, real, dimension (ilg) *QMELT*, real, dimension (ilg) *R*, real, dimension (ilg) *TR*, real, dimension (ilg) *GZERO*, real, dimension (ilg) *RALB*, real, dimension (ilg) *HMFN*, real, dimension (ilg) *HTCS*, real, dimension (ilg,ig) *HTC*, real, dimension (ilg) *FI*, real, dimension (ilg) *HCPSNO*, real, dimension (ilg) *RHOSNO*, real, dimension (ilg) *WSNOW*, integer, dimension (ilg,ig) *ISAND*, integer *IG*, integer *ILG*, integer *IL1*, integer *IL2*, integer *JL*)

Parameters

<i>htc</i>	Internal energy change of soil layer due to conduction and/or change in mass [Wm^{-2}]
<i>zsnow</i>	Depth of snow pack [m]
<i>tsnow</i>	Temperature of the snow pack [C]
<i>qmelt</i>	Energy available for melting of snow [Wm^{-2}]
<i>r</i>	Rainfall rate [ms^{-1}]
<i>tr</i>	Temperature of rainfall [C]
<i>gzero</i>	Heat flow into soil surface [Wm^{-2}]
<i>ralb</i>	Rainfall rate saved for snow albedo calculations [ms^{-1}]
<i>hmf</i>	Energy associated with freezing or thawing of water in the snow pack [Wm^{-2}]
<i>htcs</i>	Internal energy change of snow pack due to conduction and/or change in mass [Wm^{-2}]
<i>fi</i>	Fractional coverage of subarea in question on modelled area []
<i>hcpsno</i>	Heat capacity of snow pack [$Jm^{-3}K^{-1}$]
<i>rhosno</i>	Density of snow pack [kgm^{-3}]
<i>wsnow</i>	Liquid water content of snow pack [kgm^{-2}]
<i>isand</i>	Sand content flag

Melting of the snow pack occurs if a source of available energy QMELT is produced as a result of the solution of the surface energy balance, or if the snow pack temperature is projected to go above 0 C in the current time step (the available energy thus produced is added to QMELT in subroutine TSPOST). The change in internal energy in the snow pack is calculated at the beginning and end of the subroutine, and stored in diagnostic variable HTCS (see notes on subroutine SNOADD).

The calculations in the 100 loop are performed if QFREQ and the snow depth ZSNOW are both greater than zero. The available energy HADD to be applied to the snow pack is calculated from QMELT. The amount of energy required to raise the snow pack temperature to 0 C and melt it completely is calculated as HCONV. If $HADD \leq HCONV$, the depth of snow ZMELT that is warmed to 0 C and melted is calculated from HADD. (It is assumed that melting of an upper layer of snow can occur even if the lower part of the snow pack is still below 0 C.) The amount of water generated by melting the snow, RMELTS, is calculated from ZMELT, and the temperature of the meltwater TRMELT is set to 0 C. ZMELT is subtracted from ZSNOW, the heat capacity of the snow is recalculated, and HTCS is corrected for the amount of heat used to warm the removed portion of the snow pack.

If $HADD > HCONV$, the amount of available energy is sufficient to warm and melt the whole snow pack, with some energy left over. The amount of water generated by melting the snow, RMELTS, is calculated from ZSNOW, and the total amount of water reaching the soil, RMELT, is obtained by adding the liquid water content of the snow pack, WSNOW, to RMELTS. HADD is recalculated as $HADD - HCONV$, and used to calculate TRMELT. The snow depth, heat capacity, temperature and water content are set to zero, and HTCS is corrected for the amount of heat that was used to warm the snow pack to 0 C.

After the IF block, the diagnostic variable HMFN describing melting or freezing of water in the snow pack is updated using RMELTS, the temperature of the rainfall rate reaching the soil is updated using TRMELT, and RMELT is added to the rainfall rate R. QMELT is set to zero, and a flag variable RALB, used later in subroutine SNOALBW, is set to the rainfall rate reaching the ground.

In the 200 loop, a check is performed to see whether QMELT is still greater than zero and the modelled area is not an ice sheet ($ISAND > -4$). In this case QMELT is added to the ground heat flux GZERO, and the internal energy diagnostics HTCS and HTC for the snow and soil respectively are corrected. The flag variable RALB is evaluated as above.

<i>a2</i>	Work array used in calculation of GCONST and GCOEFF
<i>b1</i>	Work array used in calculation of GCONST and GCOEFF
<i>b2</i>	Work array used in calculation of GCONST and GCOEFF
<i>c2</i>	Work array used in calculation of GCONST and GCOEFF
<i>fi</i>	Fractional coverage of subarea in question on modelled area []
<i>gconst</i>	Intercept used in equation relating ground surface heat flux to surface temperature [Wm^{-2}]
<i>gcoeff</i>	Multiplier used in equation relating ground surface heat flux to surface temperature [$Wm^{-2}K^{-1}$]
<i>iwater</i>	Flag indicating condition of surface (dry, water-covered or snow-covered)
<i>isand</i>	Sand content flag
<i>delz</i>	Overall thickness of soil layer [m](Δz)

In the 100 loop, the heat flux into the ground (without adjustments that may have been applied owing to phase changes of water at the surface or partitioning the residual of the surface energy balance among the surface flux terms) is calculated from the ground surface temperature *TSURF*, using the *GCOEFF* and *GCONST* terms (see documentation of subroutine *TNPREP*). This flux is then used to back-calculate the heat conduction between the first and second, and the second and third soil layers.

If the depth of water ponded on the surface is greater than zero, the total thickness of the lumped layer consisting of the first soil layer and the ponded water, Δz_{1p} , is calculated as the sum of the two depths. The temperature of the ponded water over the subarea in question is disaggregated from the temperature of the lumped layer, T_{1p} , by making use of the calculated heat fluxes at the top and bottom of the layer, and the assumption (discussed in the documentation of subroutine *TNPREP*) that the variation of temperature *T* with depth *z* within a soil layer can be modelled using a quadratic equation:

$$T(z) = 1/2T''(0)z^2 + T'(0)z + T(0)$$

Integrating this equation separately over the ponded water depth Δz_p and over the thickness of the lumped layer produces expressions for the ponded water temperature T_p and the temperature of the lumped layer. Making use of the fact that

$$T''(0) = [T'(\Delta z) - T'(0)]/\Delta z$$

where Δz is a depth interval, and

$G(z) = -\lambda(z)T'(z)$ where λ represents the thermal conductivity, an expression for T_p can be derived:

$$T_p = [G(0)/\lambda(0) - G(\Delta z_{1p})/\lambda(\Delta z_{1p})][\Delta z_p^2 - \Delta z_{1p}^2]/6\Delta z_{1p} - G(0)[\Delta z_p - \Delta z_{1p}]/2\lambda(0) - T_{1p}$$

The temperature TBARPR of the first soil layer over the subarea in question can then be obtained by disaggregating the ponded water temperature from the lumped layer temperature using the respective heat capacities of the ponded water and the soil layer. (The heat capacity of the soil is determined as the weighted average of HCP over the permeable thickness DELZW, and the heat capacity of rock, HCPSND, over the impermeable thickness, DELZ-DELZW.) Both the ponded water temperature and the soil layer temperature are converted to C. Lastly, if there is ponded water on the surface (IWATER = 1) and QFREZG, the surface energy available for phase change of water, is positive (indicating an energy source), or if there is snow on the ground (IWATER = 2) and QFREZG is negative (indicating an energy sink), or if there is no liquid or frozen water on the surface (IWATER = 0), QFREZG is added to the heat flux into the ground, GZERO, and then reset to zero.

In loop 200, the subarea soil layer temperatures TBARPR are set for the remaining soil layers. In all cases the temperature of the layer is set to that for the modelled area, TBAR, converted to C, except in the case of the third soil layer if the standard three-layer configuration is being modelled (with a very thick third soil layer of 3.75 m). In this case TBARPR and the layer heat capacity HCP are considered to apply to the permeable depth DELZW of the layer, and the bedrock temperature TBASE and the rock heat capacity HCPSND apply to the remainder, DELZ-DELZW. The disaggregation of TBARPR from TBAR and TBASE is carried out on this basis. TBARPR for this layer is also converted to C.

<i>tcbot</i>	Thermal conductivity of soil at bottom of layer [$W m^{-1} K^{-1}$](λ_b)
<i>fi</i>	Fractional coverage of subarea in question on modelled area []
<i>zpond</i>	Depth of ponded water on surface [m]
<i>tbar1p</i>	Lumped temperature of ponded water and first soil layer [K]
<i>tcsnow</i>	Thermal conductivity of snow [$W m^{-1} K^{-1}$]
<i>zsnow</i>	Depth of snow pack [m]
<i>isand</i>	Sand content flag
<i>delz</i>	Overall thickness of soil layer [m](Δz)

In this subroutine, coefficients are derived for an equation relating the heat flux at the ground surface to the ground surface temperature, using the average temperatures and the thermal conductivities of the underlying first three soil layers. It is assumed that the variation of temperature T with depth z within each soil layer can be modelled by using a quadratic equation:

$$T(z) = (1/2)az^2 + bz + c$$

By substituting 0 for z in the above equation and in the expressions for its first and second derivatives, it can be shown that $a = T''(0)$, $b = T'(0)$, and $c = T(0)$. The term $T''(0)$ can be evaluated from the expression for the first derivative evaluated at the bottom of the soil layer, $T(\Delta z)$:

$$T''(0) = [T'(\Delta z) - T'(0)]/\Delta z$$

The temperature gradient $T'(0)$ at the top of each layer is related to the heat flux $G(0)$ through the thermal conductivity λ_t ; and the temperature gradient and heat flux at the bottom of the layer, $G(\Delta z)$ and $T(\Delta z)$, are similarly related through the bottom thermal conductivity λ_b :

$$G(0) = -\lambda_t T'(0) \quad G(\Delta z) = -\lambda_b T'(\Delta z)$$

The average soil layer temperature, $T_{av}(\Delta z)$, can be obtained by integrating the resulting equation for $T(z)$ between 0 and Δz . Making use of all of the above expressions, recognizing that the heat fluxes and temperatures at the bottoms of layers 1 and 2 must equal the heat fluxes and temperatures at the tops of layers 2 and 3 respectively, and neglecting as a first approximation the heat flux at the bottom of the third layer, a linear equation can be derived relating $G(0)$ to $T(0)$ at the soil surface, where the slope and intercept of the equation are functions only of the average temperatures, thicknesses, and top and bottom thermal conductivities of the three soil layers.

In the subroutine loop, first the depth corresponding to TBAR1P (the lumped temperature of the first soil layer and the ponded water) is calculated, as the sum of the first soil layer thickness and the ponded water depth. If the ponded water depth is not vanishingly small, the surface water flag IWATER is set to 1; otherwise it is set to 0 for soils and 2 for ice sheets (indicated by ISAND = -4). If IWATER = 2, indicating a frozen water surface, the latent heat of vaporization, CPHCHG, is set to the value for sublimation (by adding the latent heat of melting to the latent heat of vaporization). If there is a snow pack present, the thermal conductivity at the top of the ground surface is calculated as the harmonic mean of the thermal conductivity at the top of the first soil layer and that of the snow pack. Finally, a series of work arrays is evaluated and is used to calculate the slope and intercept, GCOEFF and GCONST, of the equation relating $G(0)$ to $T(0)$ at the ground surface.

Parameters

<i>tbarc</i>	Subarea temperatures of soil layers [C]
<i>tbarg</i>	Subarea temperatures of soil layers [C]
<i>tbarcs</i>	Subarea temperatures of soil layers [C]
<i>tbargs</i>	Subarea temperatures of soil layers [C]
<i>thliqc</i>	Liquid water content of soil layers under vegetation [m^3m^{-3}]
<i>thliqg</i>	Liquid water content of soil layers in bare areas [m^3m^{-3}]
<i>thicec</i>	Frozen water content of soil layers under vegetation [m^3m^{-3}]
<i>thiceg</i>	Frozen water content of soil layers in bare areas [m^3m^{-3}]
<i>hcpc</i>	Heat capacity of soil layers under vegetation [$Jm^{-3}K^{-1}$](C_g)
<i>hpcg</i>	Heat capacity of soil layers in bare areas [$Jm^{-3}K^{-1}$](C_g)
<i>tctopc</i>	Thermal conductivity of soil at top of layer in canopy-covered subareas [$Wm^{-1}K^{-1}$](λ)
<i>tcbotc</i>	Thermal conductivity of soil at bottom of layer in canopy-covered subareas [$Wm^{-1}K^{-1}$](λ)
<i>tctopg</i>	Thermal conductivity of soil at top of layer in bare ground subareas [$Wm^{-1}K^{-1}$](λ)
<i>tcbotg</i>	Thermal conductivity of soil at bottom of layer in bare ground subareas [$Wm^{-1}K^{-1}$](λ)
<i>hcpscs</i>	Heat capacity of snow pack under vegetation canopy [$Jm^{-3}K^{-1}$](C_s)
<i>hcpsgs</i>	Heat capacity of snow pack in bare areas [$Jm^{-3}K^{-1}$](C_s)
<i>tcsnow</i>	Thermal conductivity of snow [$Wm^{-1}K^{-1}$]
<i>tsnogs</i>	Temperature of snow pack in bare areas [K]
<i>tsnocs</i>	Temperature of snow pack under vegetation canopy [K]
<i>wsnocs</i>	Liquid water content of snow pack under vegetation [kgm^{-2}]
<i>wsnogs</i>	Liquid water content of snow pack in bare areas [kgm^{-2}]
<i>rhoscs</i>	Density of snow pack under vegetation canopy [kgm^{-3}]
<i>rhosgs</i>	Density of snow pack in bare areas [kgm^{-3}]
<i>tcano</i>	Temperature of canopy over ground [K]
<i>tcans</i>	Temperature of canopy over snow [K]
<i>cevap</i>	Soil evaporation efficiency coefficient β
<i>tbar1p</i>	Lumped temperature of ponded water and first soil layer [K]
<i>wtable</i>	Depth of water table in soil [m](z_{wt})
<i>zero</i>	Dummy vector containing all zeros
<i>tpondc</i>	Subarea temperature of surface ponded water [C]
<i>tpondg</i>	Subarea temperature of surface ponded water [C]
<i>tpndcs</i>	Subarea temperature of surface ponded water [C]
<i>tpndgs</i>	Subarea temperature of surface ponded water [C]
<i>ievap</i>	Flag indicating whether soil evaporation is occurring or not
<i>evapc</i>	Evaporation from vegetation over ground [ms^{-1}]
<i>evapcg</i>	Evaporation from ground under vegetation [ms^{-1}]
<i>evapg</i>	Evaporation from bare ground [ms^{-1}]
<i>evapcs</i>	Evaporation from vegetation over snow [ms^{-1}]
<i>evpcsg</i>	Evaporation from snow under vegetation [ms^{-1}]
<i>evapgs</i>	Evaporation from snow on bare ground [ms^{-1}]
<i>gsnowc</i>	Heat flux at top of snow pack under canopy [Wm^{-2}]
<i>gsnowg</i>	Heat flux at top of snow pack over bare ground [Wm^{-2}]

<i>gzeroc</i>	Subarea heat flux at soil surface [Wm^{-2}]
<i>gzerog</i>	Subarea heat flux at soil surface [Wm^{-2}]
<i>gzrocs</i>	Subarea heat flux at soil surface [Wm^{-2}]
<i>gzrogs</i>	Subarea heat flux at soil surface [Wm^{-2}]
<i>qmeltc</i>	Heat to be used for melting snow under canopy [Wm^{-2}]
<i>qmeltg</i>	Heat to be used for melting snow on bare ground [Wm^{-2}]
<i>evap</i>	Diagnosed total surface water vapour flux over modelled area [$kgm^{-2}s^{-1}$]
<i>qsensc</i>	Sensible heat flux from vegetation canopy over subarea [Wm^{-2}]
<i>qsensg</i>	Sensible heat flux from ground over subarea [Wm^{-2}]
<i>qevapc</i>	Latent heat flux from vegetation canopy over subarea [Wm^{-2}]
<i>qevapg</i>	Latent heat flux from ground over subarea [Wm^{-2}]
<i>tacco</i>	Temperature of air within vegetation canopy space over bare ground [K]
<i>qacco</i>	Specific humidity of air within vegetation canopy space over bare ground [$kgkg^{-1}$]
<i>taccs</i>	Temperature of air within vegetation canopy space over snow [K]
<i>qaccs</i>	Specific humidity of air within vegetation canopy space over snow [$kgkg^{-1}$]
<i>gsnow</i>	Diagnostic heat flux at snow surface for use in CCCma black carbon deposition scheme [Wm^{-2}]
<i>st</i>	Diagnosed screen-level air temperature [K]
<i>su</i>	Diagnosed anemometer-level zonal wind [ms^{-1}]
<i>sv</i>	Diagnosed anemometer-level meridional wind [ms^{-1}]
<i>sq</i>	Diagnosed screen-level specific humidity [$kgkg^{-1}$]
<i>srh</i>	Diagnosed screen-level relative humidity [%]
<i>cdh</i>	Surface drag coefficient for heat []
<i>cdm</i>	Surface drag coefficient for momentum []
<i>qsens</i>	Diagnosed total surface sensible heat flux over modelled area [Wm^{-2}]
<i>qevap</i>	Diagnosed total surface latent heat flux over modelled area [Wm^{-2}]
<i>qlwavg</i>	Upwelling longwave radiation over modelled area [Wm^{-2}]
<i>fsgv</i>	Diagnosed net shortwave radiation on vegetation canopy [Wm^{-2}]
<i>fsgs</i>	Diagnosed net shortwave radiation at snow surface [Wm^{-2}]
<i>fsgg</i>	Diagnosed net shortwave radiation at soil surface [Wm^{-2}]
<i>flgv</i>	Diagnosed net longwave radiation on vegetation canopy [Wm^{-2}]
<i>flgs</i>	Diagnosed net longwave radiation at snow surface [Wm^{-2}]
<i>flgg</i>	Diagnosed net longwave radiation at soil surface [Wm^{-2}]
<i>hfsc</i>	Diagnosed sensible heat flux on vegetation canopy [Wm^{-2}]
<i>hfss</i>	Diagnosed sensible heat flux at snow surface [Wm^{-2}]
<i>hfsg</i>	Diagnosed sensible heat flux at soil surface [Wm^{-2}]
<i>hevc</i>	Diagnosed latent heat flux on vegetation canopy [Wm^{-2}]
<i>hevs</i>	Diagnosed latent heat flux at snow surface [Wm^{-2}]
<i>hevg</i>	Diagnosed latent heat flux at soil surface [Wm^{-2}]
<i>hmfc</i>	Diagnosed energy associated with phase change of water on vegetation [Wm^{-2}]
<i>hmfn</i>	Diagnosed energy associated with phase change of water in snow pack [Wm^{-2}]
<i>evppot</i>	Diagnosed potential evapotranspiration [$kgm^{-2}s^{-1}$]
<i>acond</i>	Diagnosed product of drag coefficient and wind speed over modelled area [ms^{-1}]
<i>drag</i>	Surface drag coefficient under neutral stability []
<i>ilmo</i>	Surface drag coefficient under neutral stability []
<i>ue</i>	Friction velocity of air [ms^{-1}]
<i>hbl</i>	Height of the atmospheric boundary layer [m]

<i>ilmox</i>	Inverse of Monin-Obukhov roughness length over each subarea [m^{-1}]
<i>uex</i>	Friction velocity of air over each subarea [ms^{-1}]
<i>hblx</i>	Height of the atmospheric boundary layer over each subarea [m]
<i>thliq</i>	Volumetric liquid water content of soil layers [m^3m^{-3}](θ_l)
<i>thice</i>	Volumetric frozen water content of soil layers [m^3m^{-3}](θ_i)
<i>tbar</i>	Temperature of soil layers [K]
<i>zpond</i>	Depth of ponded water on surface [m]
<i>tpond</i>	Temperature of ponded water [K]
<i>ta</i>	Air temperature at reference height [K]
<i>rhosno</i>	Density of snow [kgm^{-3}](ρ_s)
<i>tsnow</i>	Snowpack temperature [K]
<i>zsnow</i>	Depth of snow pack [m](z_s)
<i>wsnow</i>	Liquid water content of snow pack [kgm^{-2}](w_s)
<i>tcn</i>	Vegetation canopy temperature [K]
<i>fc</i>	Fractional coverage of canopy over bare ground for modelled area []
<i>fcs</i>	Fractional coverage of canopy over snow for modelled area []
<i>thpor</i>	Pore volume in soil layer [m^3m^{-3}](θ_p)
<i>thlmin</i>	Residual soil liquid water content remaining after freezing or evaporation [m^3m^{-3}]
<i>thlret</i>	Liquid water retention capacity for organic soil [m^3m^{-3}](θ_{ret})
<i>thfc</i>	Field capacity [m^3m^{-3}](θ_{fc})
<i>hcps</i>	Heat capacity of soil material [$Jm^{-3}K^{-1}$](C_m)
<i>tcs</i>	Thermal conductivity of soil particles [$Wm^{-1}K^{-1}$](θ_s)
<i>delzw</i>	Permeable thickness of soil layer [m](Δz_w)
<i>zbotw</i>	Depth to permeable bottom of soil layer [m]($z_{b,w}$)
<i>delz</i>	Overall thickness of soil layer [m]
<i>isand</i>	Sand content flag

In the first two loops, various subarea arrays and internal CLASST variables are initialized. The initial temperatures of the vegetation canopy above snow and above bare ground (TCANS and TCANO) are set to the temperature of the vegetation over the whole modelled area (TCAN) if TCAN is not effectively 0 K (the value it is assigned if vegetation is not present). Otherwise, the canopy temperatures are initialized to the air temperature TA.

In loop 200 the soil surface evaporation flag IEVAP and the evaporation efficiency coefficient CEVAP are assigned. If the liquid water content of the first soil layer is effectively equal to the minimum water content THLMIN, IEVAP and CEVAP are set to zero. If the liquid water content of the first soil layer is greater than the field capacity THFC, IEVAP and CEVAP are set to unity. Otherwise, IEVAP is set to 1 and CEVAP (or β as it is typically symbolized in the literature) is calculated using a relation presented by Lee and Pielke (1992):

$$\beta = 0.25[1 - \cos(\theta_l \pi / \theta_{fc})]^2$$

where θ_l is the liquid water content of the first soil layer and θ_{fc} is its field capacity.

In loop 300 the volumetric heat capacities C_g of the soil layers under a bare surface (HCPG) and under vegetation (HCPC) are calculated, from their respective liquid and frozen water contents θ_l and θ_i :

$$C_g = C_w \theta_l + C_i \theta_i + C_m (1 - \theta_p)$$

where C_m is the heat capacity of the soil matter and θ_p is the pore volume. (The heat capacity of air is neglected.)

In loop 400, the thermal properties of the snow pack under the vegetation canopy and over bare soil are assigned on the basis of the properties of the snow pack over the whole modelled area. The heat capacity of the snow pack C_s is calculated from the volume fractions of snow particles and liquid water in the pack. The former is obtained from the ratio of the densities of the snow pack and ice, and the latter from the ratio of the liquid water content, normalized by the snow depth, and the density of water:

$$C_s = C_i [\rho_s / \rho_i] + C_w w_s / [\rho_w z_s]$$

The thermal conductivity of snow λ_s is obtained from the snow density using an empirical relationship derived by Sturm et al. (1997):

$$\lambda_s = 3.233 \times 10^{-6} \rho_s^2 + 1.01 \times 10^{-3} \rho_s + 0.138 \rho_s \geq 156.0 = 0.234 \times 10^{-3} + 0.023 < 156.0$$

In loop 500, the thermal conductivities of the soil layers are assigned. If the ISAND flag for the first soil layer is -4 (indicating glacier or ice sheet), or if the ISAND flag is -3 (indicating rock), then literature values for glacier ice

or sand particles respectively are assigned. If the ISAND flag is equal to -2, indicating organic soil, the depth of the water table z_{wt} is first calculated. This is taken to lie within the first layer, counting from the bottom of the soil profile, in which the soil water content is larger than the retention capacity θ_{ret} . The water table depth is deduced by assuming that the soil is saturated below the water table, and that the water content is at the retention capacity above it. Thus, if $\theta_l + \theta_i = \theta_p$ for the soil layer, the water table is located at the top of the soil layer; if $\theta_l + \theta_i = \theta_{ret}$, it is located at the permeable bottom of the soil layer; and if $\theta_l + \theta_i$ is between these two values, its location is given by:

$$z_{wt} = z_{b,w} - \Delta z_w [(\theta_l + \theta_i - \theta_{ret}) / (\theta_p - \theta_{ret})]$$

where Δz_w is the permeable thickness of the soil layer.

The thermal conductivities of organic and mineral soils are calculated following the analysis of Côté and Konrad (2005). They model the soil thermal conductivity λ using the concept of a relative thermal conductivity λ_r which has a value of 0 for dry soils and 1 at saturation:

$$\lambda = [\lambda_{sat} \sim \lambda_{dry}] \lambda_r + \lambda_{dry}$$

The relative thermal conductivity is obtained from the degree of saturation (the water content divided by the pore volume) S_r , using the following generalized relationship:

$$\lambda_r = \kappa S_r / [1 + (\kappa - 1) S_r]$$

The empirical coefficient kappa takes the following values:

Unfrozen coarse mineral soils: $\kappa = 4.0$

Frozen coarse mineral soils: $\kappa = 1.2$

Unfrozen fine mineral soils: $\kappa = 1.9$

Frozen fine mineral soils: $\kappa = 0.85$

Unfrozen organic soils: $\kappa = 0.6$

Frozen organic soils: $\kappa = 0.25$

The dry thermal conductivity λ_{dry} is calculated using an empirical relationship based on the pore volume θ_p , with different coefficients for mineral and organic soils:

$$\lambda_{dry} = 0.75 \exp(-2.76\theta_p)(mineral) \quad \lambda_{dry} = 0.30 \exp(-2.0\theta_p)(organic)$$

The saturated thermal conductivity λ_{sat} is calculated by Cote and Konrad (2005) [Cote2005-ew] as a geometric mean of the conductivities of the soil components. However, other researchers (e.g. Zhang et al., 2008) have found the linear averaging used by de Vries (1963) [Vries1963-ti] to be more generally accurate:

$$\lambda_{sat} = \lambda_w \theta_p + \lambda_s (1 - \theta_p)(unfrozen) \quad \lambda_{sat} = \lambda_w \theta_p + \lambda_s (1 - \theta_p)(frozen)$$

where λ_w is the thermal conductivity of water, λ_i is that of ice and λ_s is that of the soil particles.

In the 500 loop, thermal conductivities are calculated for the top and bottom of each soil layer. The degree of saturation SATRAT is calculated as the sum of liquid and frozen water contents, θ_w and θ_i , divided by the pore volume. In organic soils, if the liquid water content of the soil layer is above the retention capacity θ_{ret} , θ_w at the top of the soil layer is assumed to be equal to θ_{re} and S_r at the bottom of the layer is assumed to be 1. The relative liquid and frozen water contents, THLSAT and THISAT, are calculated from θ_w and θ_i normalized by $\theta_w + \theta_i$. The dry thermal conductivity, and the saturated thermal conductivity for unfrozen and frozen conditions, are evaluated using the equations above. The unfrozen and frozen relative thermal conductivity, TCRATU and TCRATF, are obtained from SATRAT and the appropriate values of the empirical coefficient κ . For mineral soils, κ is obtained as a weighted average over the percent sand content (ISAND converted to a real value) and the percentage of fine material (assumed to be 100-ISAND). The unfrozen and frozen soil thermal conductivities, TCSOLU and TCSOLF, are then calculated from TCRATU, TCRATF, and the dry and saturated thermal conductivities; and the actual thermal conductivity of the soil, TCSOIL, is determined as the average of TCSOLU and TCSOLF, weighted according to the relative liquid and frozen water contents THLSAT and THISAT. If the permeable thickness of the layer, DELZW, is greater than zero, the thermal conductivity at the top of the layer is set to TCSOIL; otherwise it is set to the rock value, TCSAND. If DELZW is less than the thermal thickness of the layer DELZ, the thermal conductivity at the bottom of the layer is set to TCSAND; otherwise it is set to TCSOIL. (In the case of organic soils in the latter branch, if θ_w was greater than θ_{ret} , the thermal conductivity at the bottom of the layer is set to the average of the saturated unfrozen and frozen values, weighted by THLSAT and THISAT.) Finally, if there is ponded water present on the soil surface, the thermal conductivity at the top of the first soil layer is treated as varying linearly from the calculated soil thermal conductivity if the pond depth ZPOND is zero, to the thermal conductivity of water if $ZPOND \geq 10^{-2}m$.

Finally, in loop 600, a variable TBAR1P is evaluated, representing the weighted average value of the first layer soil temperature and the ponded water, if any. (The heat capacity of the soil is determined as the weighted average of HCPG over the permeable thickness DELZW, and the heat capacity of rock, HCPSND, over the impermeable thickness, DELZ-DELZW.)

Parameters

<i>isnow</i>	Flag indicating presence or absence of snow
<i>qswnet</i>	Total net shortwave radiation of canopy and underlying surface [Wm^{-2}]
<i>qswnc</i>	Net shortwave radiation on vegetation canopy [Wm^{-2}](K_{*c})
<i>qswng</i>	Net shortwave radiation at underlying surface [Wm^{-2}](K_{*g})
<i>qlwout</i>	Upwelling longwave radiation from canopy and underlying surface [Wm^{-2}]
<i>qlwoc</i>	Upwelling longwave radiation from vegetation canopy [Wm^{-2}]($L_{\uparrow c}, L_{\downarrow c}$)
<i>qlwog</i>	Upwelling longwave radiation from underlying surface [Wm^{-2}]($L_{\uparrow g}$)
<i>qtrans</i>	Shortwave radiation transmitted into surface [Wm^{-2}]
<i>qsens</i>	Sensible heat flux from canopy and underlying surface [Wm^{-2}](Q_H)
<i>qsensc</i>	Sensible heat flux from vegetation canopy [Wm^{-2}]($Q_{H,c}$)
<i>qsensg</i>	Sensible heat flux from underlying surface [Wm^{-2}]($Q_{H,g}$)
<i>qevap</i>	Latent heat flux from canopy and underlying surface [Wm^{-2}](Q_E)
<i>qevapc</i>	Latent heat flux from vegetation canopy [Wm^{-2}]($Q_{E,c}$)
<i>qevapg</i>	Latent heat flux from underlying surface [Wm^{-2}]($Q_{E,g}$)
<i>evapc</i>	Evaporation rate from vegetation [$kgm^{-2}s^{-1}$](E_c)
<i>evapg</i>	Evaporation rate from underlying surface [$kgm^{-2}s^{-1}$]($E(0)$)
<i>tcan</i>	Vegetation canopy temperature [K](T_c)
<i>qcan</i>	Saturated specific humidity at canopy temperature [$kgkg^{-1}$](q_c)
<i>tzero</i>	Temperature at surface [K]($T(0)$)
<i>qzero</i>	Specific humidity at surface [$kgkg^{-1}$]($q(0)$)
<i>gzero</i>	Heat flux into surface [Wm^{-2}]($G(0)$)
<i>qmeltc</i>	Heat available for melting snow or freezing water on the vegetation [Wm^{-2}]
<i>qmeltg</i>	Heat available for melting snow or freezing water on the underlying surface [Wm^{-2}]
<i>raican</i>	Intercepted liquid water stored on vegetation canopy [kgm^{-2}]
<i>snocan</i>	Intercepted frozen water stored on vegetation canopy [kgm^{-2}]
<i>cdh</i>	Surface drag coefficient for heat []
<i>cdm</i>	Surface drag coefficient for momentum []
<i>rib</i>	Bulk Richardson number at surface []
<i>tac</i>	Temperature of air within vegetation canopy [K](T_{ac})
<i>qac</i>	Specific humidity of air within vegetation canopy space [$kgkg^{-1}$](q_{ac})
<i>cflux</i>	Product of surface drag coefficient and wind speed [ms^{-1}]
<i>ftemp</i>	Product of surface-air temperature gradient, drag coefficient and wind speed [Kms^{-1}]
<i>fvap</i>	Product of surface-air humidity gradient, drag coefficient and wind speed [$kgkg^{-1}ms^{-1}$]
<i>ilmo</i>	Inverse of Monin-Obukhov roughness length (m^{-1})
<i>ue</i>	Friction velocity of air [ms^{-1}]
<i>h</i>	Height of the atmospheric boundary layer [m]
<i>qfcf</i>	Sublimation from frozen water on vegetation [$kgm^{-2}s^{-1}$]
<i>qfcl</i>	Evaporation from liquid water on vegetation [$kgm^{-2}s^{-1}$]
<i>htcc</i>	Internal energy change of canopy due to changes in temperature and/or mass [Wm^{-2}]
<i>evap</i>	Diagnosed total surface water vapour flux over modelled area [$kgm^{-2}s^{-1}$]
<i>fi</i>	Fractional coverage of subarea in question on modelled area []
<i>qswinv</i>	Visible radiation incident on horizontal surface [Wm^{-2}](K_{\downarrow})
<i>qswini</i>	Near-infrared radiation incident on horizontal surface [Wm^{-2}](K_{\downarrow})
<i>qlwin</i>	Downwelling longwave radiation at bottom of atmosphere [Wm^{-2}](L_{\downarrow})

<i>tpota</i>	Potential temperature of air at reference height $[K](T_{a,pot})$
<i>ta</i>	Air temperature at reference height $[K]$
<i>qa</i>	Specific humidity at reference height $[kgkg^{-1}](q_a)$
<i>va</i>	Wind speed at reference height $[ms^{-1}]$
<i>vac</i>	Wind speed within vegetation canopy space $[ms^{-1}](v_{ac})$
<i>padry</i>	Partial pressure of dry air $[Pa](p_{dry})$
<i>rhoair</i>	Density of air $[kgm^{-3}](\rho_a)$
<i>alvisc</i>	Visible albedo of vegetation canopy $[(\alpha_c)]$
<i>alnirc</i>	Near-IR albedo of vegetation canopy $[(\alpha_c)]$
<i>alvisg</i>	Visible albedo of underlying surface $[(\alpha_g)]$
<i>alnirg</i>	Near-IR albedo of underlying surface $[(\alpha_g)]$
<i>trvisc</i>	Visible transmissivity of vegetation canopy $[(\tau_c)]$
<i>trnirc</i>	Near-IR transmissivity of vegetation canopy $[(\tau_c)]$
<i>fsvf</i>	Sky view factor of ground underlying canopy $[(\chi)]$
<i>crib</i>	Richardson number coefficient $[K^{-1}]$
<i>cphchc</i>	Latent heat of vaporization on vegetation canopy $[Jkg^{-1}](L_v)$
<i>cphchg</i>	Latent heat of vaporization on underlying ground $[Jkg^{-1}](L_v)$
<i>cevap</i>	Soil evaporation efficiency coefficient $[-]$
<i>tadp</i>	Dew point of air at reference height $[K]$
<i>tvirta</i>	Virtual potential temperature of air at reference height $[K](T_{a,v})$
<i>rc</i>	Stomatal resistance of vegetation $[sm^{-1}](r_c)$
<i>rbcoef</i>	Parameter for calculation of leaf boundary resistance
<i>zosclh</i>	Ratio of roughness length for heat to reference height for temperature and humidity $[-]$
<i>zosclm</i>	Ratio of roughness length for momentum to reference height for wind speed $[-]$
<i>zrslfh</i>	Difference between reference height for temperature and humidity and height at which extrapolated wind speed goes to zero $[m]$
<i>zrslfm</i>	Difference between reference height for wind speed and height at which extrapolated wind speed goes to zero $[m]$
<i>zoh</i>	Surface roughness length for heat $[m]$
<i>zom</i>	Surface roughness length for momentum $[m](z_{0,m})$
<i>fcor</i>	Coriolis parameter $[s^{-1}]$
<i>gconst</i>	Intercept used in equation relating surface heat flux to surface temperature $[Wm^{-2}]$
<i>gcoeff</i>	Multiplier used in equation relating surface heat flux to surface temperature $[Wm^{-2}K^{-1}]$
<i>tgnd</i>	Starting point for surface temperature iteration $[K]$
<i>trsnow</i>	Short-wave transmissivity of snow pack $[-]$
<i>fsnowc</i>	Fractional coverage of canopy by frozen water $[(F_s)]$
<i>frainc</i>	Fractional coverage of canopy by liquid water $[(F_l)]$
<i>chcap</i>	Heat capacity of vegetation canopy $[Jm^{-2}K^{-1}](C_c)$
<i>cmass</i>	Mass of vegetation canopy $[kgm^{-2}]$
<i>pcpr</i>	Surface precipitation rate $[kgm^{-2}s^{-1}]$
<i>rhosno</i>	Density of snow $[kgm^{-3}]$
<i>zsnow</i>	Depth of snow pack $[m](z_s)$
<i>froot</i>	Fraction of total transpiration contributed by soil layer $[-]$
<i>thlmin</i>	Residual soil liquid water content remaining after freezing or evaporation $[m^3m^{-3}]$
<i>thliq</i>	Volumetric liquid water content of soil layers $[m^3m^{-3}]$
<i>delzw</i>	Permeable thickness of soil layer $[m]$
<i>iwater</i>	Flag indicating condition of surface (dry, water-covered or snow-covered)
<i>ievap</i>	Flag indicating whether surface evaporation is occurring or not output variable

<i>iterct</i>	Counter of number of iterations required to solve energy balance for four subareas
---------------	--

For the subcanopy surface temperature iteration, two alternative schemes are offered: the bisection method (selected if the flag ITCG = 1) and the Newton-Raphson method (selected if ITCG = 2). In the first case, the maximum number of iterations ITERM is set to 12, and in the second case it is set to 5. An optional windless transfer coefficient EZERO is made available, which can be used, following the recommendations of Brown et al. (2006) [Brown2006-ec], to prevent the sensible heat flux over snow packs from becoming vanishingly small under highly stable conditions. If the snow cover flag ISNOW is zero (indicating bare ground), EZERO is set to zero; if ISNOW=1, EZERO is set to $2.0 W m^{-2} K^{-1}$. The surface transfer coefficient under conditions of free convection, RAGCO, is set to 1.9×10^{-3} (see the calculation of RAGINV below).

In the 50 loop, some preliminary calculations are done. The shortwave transmissivity at the surface, TRTOP, is set to zero in the absence of a snow pack, and to the transmissivity of snow, TRSNOW, otherwise. The net shortwave radiation at the surface, QSWNG, is calculated as the sum of the net visible and net near-infrared shortwave radiation. Each of these is obtained as: $K_{*g} = K \downarrow \tau_c [1 - \alpha_g]$ where K_{*g} is the net radiation at the surface, K is the incoming shortwave radiation above the canopy, τ_c is the canopy transmissivity and α_g is the surface albedo. This average value is corrected for the amount of radiation transmitted into the surface, QTRANS, obtained using TRTOP. The net shortwave radiation for the vegetation canopy, QSWNC, is calculated as the sum of the net visible and net near-infrared shortwave radiation. Each of these is determined as: $K_{*c} = K \downarrow [1 - \alpha_c] - K_{*g}$ where K_{*c} is the net radiation on the canopy and α_c is the canopy albedo. If the canopy temperature is essentially 0 K, indicating that a canopy was not present in the previous time step but has now appeared, the canopy temperature is initialized to the potential temperature of the air, TPOTA. The outgoing longwave radiation emitted upward ($L \uparrow_c$) or downward ($L \downarrow_c$) from the canopy is calculated using the standard Stefan-Boltzmann equation: $L \uparrow_c = L \downarrow_c = \sigma T_c^4$ where σ is the Stefan-Boltzmann constant and T_c is the canopy temperature.

Virtual temperature is defined as temperature adjusted for the reduction in air density due to the presence of water vapour. This is applied in order to enable the use of the equation of state for dry air. The virtual temperature can be approximated by multiplying the actual temperature by a factor $[1 + 0.61 q]$, where q is the specific humidity of the air in question. Thus, the virtual temperature of air at the vegetation canopy temperature, $T_{c,v}$, is obtained as: $T_{c,v} = T_c [1 + 0.61 q_c]$ where q_c is the saturated specific humidity at the canopy temperature. This is determined from the saturation mixing ratio at the canopy temperature, w_c : $q_c = w_c / [1 + w_c]$. The saturation mixing ratio is a function of the saturation vapour pressure e_c at the canopy temperature: $w_c = 0.622 e_c / (p_{dry})$ where p_{dry} is the partial pressure of dry air. A standard empirical equation for the saturation vapour pressure dependence on the temperature T is used:

$$e_{sat} = 611.0 \exp[17.269(T - T_f)/(T - 35.86)] \quad T \geq T_f \quad e_{sat} = 611.0 \exp[21.874(T - T_f)/(T - 7.66)] \quad T < T_f$$

where T_f is the freezing point. The virtual temperature of the air in the canopy space, $T_{ac,v}$, is likewise calculated from the canopy air temperature T_{ac} and the specific humidity in the canopy air space, q_{ac} , as

$$T_{ac,v} = T_{ac} [1 + 0.61 q_{ac}]$$

If the Newton-Raphson method is being used for the canopy temperature iteration (pre-selected by setting the flag ITC to 2), the temperature of the air in the canopy space is approximated as the canopy temperature, and the specific humidity in the canopy air space is approximated as the specific humidity of the air above the canopy.

If there is intercepted snow on the vegetation, the latent heat associated with water flux from the canopy, CPHCHC, is set to the latent heat of sublimation (the sum of the heat of vaporization and the heat of melting). Otherwise the latent heat is set to that of vaporization alone. The leaf boundary layer resistance R_b , and its inverse R_{bINV} , are calculated using the wind speed in the canopy air space, V_{ac} , and a coefficient R_{bCOEF} evaluated in subroutine APREP. This coefficient is formulated after Bartlett (2004), who developed an expression for the inverse of the leaf boundary resistance, $1/r_b$, drawing on the analysis of Bonan (1996) [Bonan1996-as] and McNaughton and van den Hurk (1995), of the form:

$$1/r_b = v_{ac}^{1/2} \sigma f_i \gamma_i \Lambda_i^{1/2} / 0.75 [1 - \exp(-0.75 \Lambda_i^{1/2})]$$

where v_{ac} is the wind speed in the canopy air space, f_i is the fractional coverage of each vegetation type i over the subarea in question, Λ_i is its leaf area index, and γ_i is a vegetation-dependent parameter which incorporates the effects of leaf dimension and sheltering. The initial value of the surface temperature TZERO is set to TGND, which contains the value of TZERO from the previous time step, and the initial temperature of the canopy, TCANO, is set to the current canopy temperature. The first step in the iteration sequence, TSTEP, is set to 1.0 K. The flag ITER is set to 1 for each element of the set of modelled areas, indicating that its surface temperature has not yet been found. The iteration counter NITER is initialized to 1 for each element. Initial values are assigned to other

variables. In particular, the maximum evaporation from the ground surface that can be sustained for the current time step is specified as the total snow mass if snow is present, otherwise as the total available water in the first soil layer.

(At this point in the code, if CLASS is being run in coupled mode with CTEM, the CTEM subroutine PHTSYN3 is called. These lines are commented out for uncoupled runs.)

The 100 continuation line marks the beginning of the surface temperature iteration sequence. First the flag NUMIT (indicating whether there are still locations at the end of the current iteration step for which the surface temperature has not yet been found) is set to zero. Loop 125 is then performed over the vector of modelled areas. If ITER=1, the saturated specific humidity at the ground surface temperature, $q(0)_{sat}$, is calculated using the same method as that outlined above for the saturated specific humidity at the canopy temperature. If there is a snow cover or ponded water present on the surface (IWATER > 0), the surface evaporation efficiency EVBETA is set to 1 and the surface specific humidity $q(0)$ is set to $q(0)_{sat}$. Otherwise EVBETA is set to CEVAP, the value obtained in subroutine TPREP on the basis of ambient conditions, and $q(0)$ is calculated from $q(0)_{sat}$ by making use of the definition of the surface evaporation efficiency β :

$$\beta = [q(0) - q_{ac}] / [q(0)_{sat} - q_{ac}]$$

which is inverted to obtain an expression for $q(0)$. If $q(0) > q_{ac}$ and the evaporation flag IEVAP has been set to zero, EVBETA is reset to zero and $q(0)$ is reset to q_{ac} .

Next, the potential temperature of air at the ground surface temperature, $T(0)_{pot}$, is calculated relative to the sum of the displacement height d and the roughness length for momentum $z_{0,m}$, the height at which the canopy temperature is assumed to apply. (This is also the height corresponding to the potential temperature of the air at the reference height above the canopy). $T(0)_{pot}$ is found using the dry adiabatic lapse rate, $dT/dz = -g/c_p$, where g is the acceleration due to gravity and c_p is the specific heat at constant pressure. Since the displacement height d is assumed to lie at 0.7 of the canopy height, and the roughness length for momentum is assumed to lie at 0.1 of the canopy height, their sum can be obtained as $8.0z_{0,m}$. Thus, $T(0)_{pot} = T(0) - 8.0z_{0,m}g/c_p$

The virtual potential temperature at the surface is obtained using the same expression as above: $T(0)_v = T(0)_{pot}[1 + 0.61q(0)]$

Since wind speeds under the canopy are expected to be relatively small, it is assumed that under stable or neutral conditions, turbulent fluxes are negligible. If the virtual potential temperature of the surface is more than 1 K greater than that of the canopy air, free convection conditions are assumed. Townsend's (1964) equation for the surface-air transfer coefficient, or the inverse of the surface resistance $r_{a,g}$, is used in a form derived from the analysis of Deardorff (1972) [Deardorff1972-ay]: $1/r_{a,g} = 1.9 \times 10^{-3} [T(0)_v - T_{ac,v}]^{1/3}$

The first derivative of the transfer coefficient with respect to the surface temperature is calculated for use with the Newton-Raphson iteration scheme: $d(1/r_{a,g})/dT = 1.9 \times 10^{-3} [T(0)_v - T_{ac,v}]^{-2/3} / 3$

If the virtual potential temperature of the surface is between 0.001 and 1 K greater than that of the canopy air, a simple diffusion relation is assumed: $1/r_{a,g} = 1.9 \times 10^{-3} [T(0)_v - T_{ac,v}]$ Thus, $d(1/r_{a,g})/dT = 1.9 \times 10^{-3}$

The remaining terms of the surface energy balance are now evaluated. The energy balance equation is expressed as: $K_{*g} + L_{*g} - Q_{H,g} - Q_{E,g} - G(0) = 0$ where K_{*g} is the net surface shortwave radiation, L_{*g} is the net longwave radiation, $Q_{H,g}$ is the sensible heat flux, $Q_{E,g}$ is the latent heat flux, and $G(0)$ is the conduction into the surface. K_{*g} was evaluated earlier in loop 50. L_{*g} is calculated as the difference between the downwelling radiation $L \downarrow_g$ at the surface and the upwelling radiation $L \uparrow_g$. The downwelling radiation incident on the surface is determined from the downwelling sky radiation above the canopy $L \downarrow$ and the downwelling radiation from the canopy itself, $L \downarrow_c$, weighted according to the sky view factor χ : $L \downarrow_g = \chi L \downarrow + [1 - \chi] L \downarrow_c$. The upwelling radiation is obtained using the Stefan-Boltzmann equation: $L \uparrow_g = \sigma T(0)^4$

The sensible heat flux is given by $Q_{H,g} = \rho_a c_p [T(0)_{pot} - T_{a,c}] / r_{a,g}$ where ρ_a is the density of the air and c_p is its specific heat. (The windless transfer coefficient defined at the beginning of the subroutine is currently not used under vegetation canopies.) The evaporation rate at the surface, $E(0)$, is calculated as $E(0) = \rho_a [q(0) - q_{a,c}] / r_{a,g}$

The evaporation rate is constrained to be less than or equal to the maximum rate evaluated earlier in the subroutine. Q_E is obtained by multiplying $E(0)$ by the latent heat of vaporization at the surface. The heat flux into the surface $G(0)$ is determined as a linear function of $T(0)$ (see documentation for subroutines TNPREP and TSPREP). It can be seen that each of the terms of the surface energy balance is a function of a single unknown, $T(0)$ or TZERO. The residual RESID of the energy balance is now evaluated on the basis of the current estimation for TZERO. If the absolute value of RESID is less than $5.0 W m^{-2}$, or if the absolute value of the iteration step TSTEP most recently used is less than 0.01 K, the surface temperature is deemed to have been found and ITER is set to 0. If the iteration

counter NITER is equal to the maximum number and ITER is still 1, ITER is set to -1.

In the following section, the iteration sequence is moved ahead a step. If ITCG = 1, the calculations for the bisection method of solution in loop 150 are performed, over each of the modelled areas for which ITER = 1. If NITER = 1 (indicating that this is the first step in the iteration), then if RESID > 0 (indicating that the current value for TZERO had undershot the correct value), TZERO is incremented by 1 K; otherwise it is decremented by 1 K. If this is not the first step in the iteration, then if RESID > 0 and TSTEP < 0 (indicating that TZERO has undershot the correct value and the last temperature increment had been a negative one) or if RESID < 0 and TSTEP > 0 (indicating that TZERO has overshot the correct value and the last temperature increment had been a positive one), TSTEP is divided in half and its sign changed. TSTEP is then added to TZERO. The iteration counter NITER and the flag NUMIT are each incremented by one. Finally, if NUMIT > 0, the iteration cycle is repeated from line 100 on.

If ITCG = 2, the calculations for the Newton-Raphson method of iteration in loop 175 are performed, over each of the modelled areas for which ITER = 1. In this approach, the value x_{n+1} used at each iteration step is obtained from the value x_n at the previous step as follows: $x_{n+1} = x_n - f(x_n)/f'(x_n)$

Identifying x_n with TZERO and $f(x_n)$ with the surface energy balance equation, it can be seen that the second term on the right-hand side corresponds to TSTEP; the numerator is equal to RESID and the denominator to the first derivative of the energy balance equation evaluated at TZERO, which in turn is equal to the sum of the derivatives of the individual terms: $f[d(L)/dT = -4 T(0)^3 f[d(Q_{H,g})/dT = c_p \{1/r_{a,g} + [T(0)_{pot} - T_{ac}] d(1/r_{a,g})/dT\} f[d(Q_{E,g})/dT = L_v \{1/r_{a,g} dq(0)/dT + [q(0) - q_{ac}] d(1/r_{a,g})/dT\} f]$ and $dG(0)/dT$ is equal to the coefficient multiplying TZERO in the equation for $G(0)$. (L_v is the latent heat of vaporization at the surface.) At the end of the calculations the iteration counter NITER and the flag NUMIT are each incremented by one, and upon exiting the loop, if NUMIT > 0, the iteration cycle is repeated from line 100 on.

After the iteration has been completed, if the Newton-Raphson method has been used, a check is carried out in loop 200 to ascertain whether convergence has not been reached (i.e. whether ITER = -1) for any location. In such cases it is assumed that conditions of near-neutral stability at the surface are the cause of the difficulty in finding a solution. A trial value of TZERO is calculated using the virtual potential temperature of the canopy. If the absolute value of RESID is $> 15 W m^{-2}$, TZERO is set to this trial value. The values of $q(0)$ and the components of the surface energy balance are recalculated as above, except that $Q_{H,g}$ and $Q_{E,g}$ are assumed as a first approximation to be zero. RESID is determined on this basis, and is then partitioned between $Q_{H,g}$ and $Q_{E,g}$ on the basis of the Bowen ratio B, the ratio of $Q_{H,g}$ over $Q_{E,g}$. Setting the residual R equal to $Q_{H,g} + Q_{E,g}$, and substituting for $Q_{H,g}$ using $B = Q_{H,g}/Q_{E,g}$, results in: $Q_{E,g} = R/(1 + B)$ $Q_{H,g}$ is then obtained as $R - Q_{E,g}$, the residual is reset to zero, and $E(0)$ is recalculated from $Q_{E,g}$.

At this point a check is performed for unphysical values of the surface temperature, i.e. for values greater than 100 C or less than -100 C. If such values are encountered, an error message is printed and a call to abort is carried out.

Finally, clean-up calculations are performed in loop 250. A check is carried out to ensure that TZERO is not less than 0 C if ponded water is present on the surface (IWATER = 1) or greater than 0 C if snow is present on the surface (IWATER = 2). If either is the case, TZERO is reset to the freezing point, and $q(0)$, $T(0)_{pot}$ and $T(0)_v$ are re-evaluated. The components of the surface energy balance are recalculated using the above equations. The residual of the energy balance equation is assigned to the energy associated with phase change of water at the surface, QMELTG, and RESID is set to zero.

In the last part of the loop, some final adjustments are made to a few other variables. If the evaporation flux is vanishingly small, it is added to RESID and reset to zero. Any remaining RESID is added to $Q_{H,g}$. Lastly, the iteration counter ITERCT is updated for the level corresponding to the subarea type and the value of NITER.

In the 300 loop, preliminary calculations are done in preparation for the canopy temperature iteration. The sensible heat flux from the surface is treated differently if ITC = 1 (bisection method of solution) and ITC = 2 (Newton-Raphson method of solution). In the first instance the surface sensible heat flux is applied to heating the air in the canopy space; in the second, the canopy and the air space within it are treated as one aggregated mass, and the sensible heat flux from below is assumed to be added to its energy balance. Thus, if ITC = 1, the sensible heat flux that is added to the canopy, QSGADD, is set to 0. If ITC = 2, it is set to $Q_{H,g}$; and T_{ac} is set to T_c , q_{ac} to q_c , and $T_{ac,v}$ to $T_{c,v}$. The flag ITER is set to 1 for each element of the set of modelled areas, indicating that its surface temperature has not yet been found. The iteration counter NITER is initialized to 1 for each element. The first step in the iteration sequence, TSTEP, is set to 1.0 K. Initial values are assigned to other variables. In the following 350 loop, the water available for transpiration, WAVAIL, is evaluated for each soil layer. Lastly, after exiting the loop, the maximum number of iterations ITERMX is set to 50 if ITC = 1, and to 5 if ITC = 2.

The 400 continuation line marks the beginning of the canopy temperature iteration sequence. First the flags N←

IT (indicating whether there are still locations at the beginning of the current iteration step for which the surface temperature has not yet been found) and NUMIT (indicating whether there are still locations at the end of the current iteration step for which the surface temperature has not yet been found) are set to zero. Loop 450 is then performed over the set of modelled areas. If ITER=1, NIT is incremented by one; if ITC = 1, the vegetation virtual temperature $T_{c,v}$ is recalculated.

If NIT > 0, a subroutine is called to evaluate the stability-corrected surface drag coefficients for heat and momentum. The subroutine selection is made on the basis of the flag ISLFD. If ISLFD=1, indicating that the calculations are to be consistent with CCCma conventions, subroutine DRCOEF is called; if ISLFD=2, indicating that the calculations are to be consistent with RPN conventions, subroutine FLXSURFZ is called.

Next, canopy parameters and turbulent transfer coefficients are calculated prior to evaluating the terms of the surface energy balance equation. If ITC = 1, the analysis of Garratt (1992) [Garratt1992-dt] is followed. The sensible and latent heat fluxes from the canopy air to the overlying atmosphere, Q_H and Q_E , are obtained as the sums of the sensible and latent heat fluxes from the canopy to the canopy air, $Q_{H,c}$ and $Q_{E,c}$, and from the underlying surface to the canopy air, $Q_{H,g}$ and $Q_{E,g}$:

$$Q_H = Q_{H,c} + Q_{H,g}$$

$$Q_E = Q_{E,c} + Q_{E,g}$$

where

$$Q_H = \rho_a c_p [T_{a,c} - T_{a,pot,}] / r_a$$

$$Q_{H,c} = \rho_a c_p [T_c - T_{a,c,}] / r_b$$

and

$$Q_E = L_v \rho_a [q_{a,c} - q_a,] / r_a$$

$$Q_{E,c} = L_v \rho_a [q_{c,c} - q_{a,c,}] / (r_b + r_c)$$

The equations for the sensible and latent heat fluxes from the surface were presented above. In these expressions, $T_{a,pot}$ and q_a are the potential temperature and specific humidity of the air overlying the canopy, is the aerodynamic resistance to turbulent transfer between the canopy air and the overlying air, and is the stomatal resistance. r_a . Thus, $T_{a,c}$ and $q_{a,c}$ can be evaluated as $\{a,c\} = [T_{a,pot} / r_a + T_c / r_b + T(0)_{pot} / r_{a,g}] / [1/r_a + 1/r_b + 1/r_{a,g}]$ $\{a,c\} = [q_a / r_a + q_c / (r_b + r_c) + q(0)_{a,g} / r_{a,g}] / [1/r_a + 1/(r_b + r_c) + 1/r_{a,g}]$ If the water vapour flux is toward the canopy leaves, or if the canopy is snow-covered or rain-covered, is zero. If the water vapour flux is away from the canopy leaves and the fractional snow or water coverage on the canopy, or $F_i / (r_b + r_c)$ adjusted for the presence of intercepted snow or water, (XEVAP in the code) is calculated as a weighted average $F_s > 0$, the canopy must be at a temperature of 0°C or less, and so it is deduced that no transpiration can be occurring. Thus, $F_s = (F_s + F_i) / r_b$. Otherwise, is calculated on the assumption that the resistance is equal to r_b over the water-covered area and r_c over the rest: $F_i / r_b + [1 - F_i] / [r_b + r_c]$

In the 450 loop, XEVAP is first set as a trial value to RBLNV (neglecting stomatal resistance), and QAC is calculated using this value. If $q_{a,c} < q_c$, indicating that the vapour flux is away from the canopy leaves, XEVAP is recalculated as above and QAC is re-evaluated. Otherwise, if $F_s > 0$, XEVAP is scaled by F_s , since it is assumed that snow on the canopy will be at a lower temperature than the canopy itself, and deposition via sublimation will occur preferentially onto it. $T_{a,c}$ and $T_{ac,v}$ are calculated as above, and the canopy-air turbulent transfer coefficients for sensible and latent heat flux, CFSSENS and CFEVAP, are set to RBLNV and XEVAP respectively.

If ITC = 2, the canopy parameters and turbulent transfer coefficients are calculated, as noted above, on the basis of the assumption that the vegetation canopy and the air space within it can be treated as one aggregated mass, with a single representative temperature. Thus, the resistances r_a and r_b are considered as acting in series upon the sensible and latent heat fluxes between the canopy and the overlying air:

$$Q_{H,c} = \rho_a c_p [T_c - T_{a,pot,}] / (r_a + r_b)$$

$$Q_{E,c} = L_v \rho_a [q_{c,c} - q_a,] / (r_a + r_b + r_c)$$

In loop 500 the term $1/(r_a + r_b)$ is calculated from the variables CFLUX (the inverse of r_a) and RBLNV (the inverse of r_b), and assigned to the temporary variable CFLX. If the incoming visible shortwave radiation QSWINV is greater than or equal to $25 W m^{-2}$, the calculated value of CFLX is retained; if QSWINV is zero, it is reset to CFLUX; and between these two limits it varies linearly between the two.

Thus the effect of the calculated leaf boundary resistance is suppressed during conditions of zero or low solar

heating. (This is done to avoid unrealistically low calculated turbulent fluxes at night, which can lead to anomalously low canopy temperatures.) The overall aerodynamic resistance $r_A = r_a + r_b$ is obtained as $1/\text{CFLX}$ and assigned to the variable RA. As with $\text{ITC} = 1$, if $q_a < q_c$, XEVAP is recalculated as above (except that r_A is substituted for r_b). If $F_s > 0$, XEVAP is again scaled by F_s .

In the approach used here, the specific humidity of the aggregated canopy $q_{0,c}$ is not assumed to be equal to the saturated specific humidity at the canopy temperature, but is rather determined using X_E . If the two methods of calculating $Q_{E,c}$ are assumed to be analogous:

$$Q_{E,c} = L_v \rho_a X_E [q_{0,c} - q_a]$$

$$Q_{E,c} = L_v \rho_a [q_{0,c} - q_a] / r_A$$

then solving for $q_{0,c}$ leads to the expression

$$q_{0,c} = r_A X_E q_c + [1 - r_A X_E] q_a$$

In the second part of the 500 loop the saturated specific humidity of the canopy is calculated as before and adjusted using the above equation to obtain the specific humidity of the aggregated canopy. This is then used to calculate $T_{c,v}$. The canopy-air turbulent transfer coefficients for sensible and latent heat flux, CFSSENS and CFEVAP, are both set to CFLX, and for calculation purposes in the following loop $T_{a,c}$ is set to the potential temperature of the air above the canopy, and $q_{a,c}$ to the specific humidity of the air above the canopy.

In the 525 loop, the terms of the canopy energy balance are evaluated. The energy balance is expressed as:

$$K_{*c} + L_{*c} - Q_{H,c} + Q_{H,g+} - Q_{E,c} - \Delta Q_{S,c} = 0$$

(The term $Q_{H,g+}$ corresponds to the variable QSGADD discussed above; the term $\Delta Q_{S,c}$ represents the change of energy storage in the canopy.) The net shortwave radiation K_{*c} was evaluated earlier in the 50 loop. The net longwave radiation is obtained as:

$$L_{*c} = (1 - \chi)[L \downarrow + L \uparrow_g - 2L \downarrow_c]$$

$Q_{H,c}$ is calculated as above. If there is intercepted liquid or frozen water on the canopy, or if the vapour flux is downward, or if the stomatal resistance is less than a limiting high value of 5000 sm^{-1} , the canopy vapour flux E_c (that is, $Q_{E,c}/L_v$) is calculated as above and the flag IEVAPC is set to 1; otherwise E_c and IEVAPC are both set to zero and q_c is set to q_a . If the water vapour flux is towards the canopy and the canopy temperature is greater than the air dew point temperature, the flux is set to zero. In the following IF block, checks are done to ensure that the calculated canopy evapotranspiration flux will not exceed the available water. If intercepted snow is present on the canopy, the maximum evapotranspiration is set to this amount. Otherwise, if the calculated evapotranspiration rate exceeds the liquid water stored on the canopy, the rate is tested to ensure that the additional transpiration does not exhaust the available soil water weighted according to the root distribution. $Q_{E,c}$ is calculated from E_c and $\Delta Q_{S,c}$ is obtained as

$$\Delta Q_{S,c} = C_c [T_c - T_{c,o}] / \Delta t$$

where C_c is the canopy heat capacity, $T_{c,o}$ is the canopy temperature from the previous time step and Δt is the length of the time step. The residual RESID of the energy balance is evaluated on the basis of the current estimation for the canopy temperature TCAN. If the absolute value of RESID is less than 5.0 W m^{-2} , or if the absolute value of the iteration step TSTEP most recently used is less than 0.01 K, the surface temperature is deemed to have been found and ITER is set to 0. If the iteration counter NITER is equal to the maximum number and ITER is still 1, ITER is set to -1.

In the following section, the iteration sequence is moved ahead a step. If $\text{ITC} = 1$, the calculations for the bisection method of solution in loop 550 are performed, over each of the modelled areas for which $\text{ITER} = 1$. If $\text{NITER} = 1$ (indicating that this is the first step in the iteration), then if $\text{RESID} > 0$ (indicating that the current value for TCAN had undershot the correct value), TCAN is incremented by 1 K; otherwise it is decremented by 1 K. If this is not the first step in the iteration, then if $\text{RESID} > 0$ and $\text{TSTEP} < 0$ (indicating that TCAN has undershot the correct value and the last temperature increment had been a negative one) or if $\text{RESID} < 0$ and $\text{TSTEP} > 0$ (indicating that TCAN has overshot the correct value and the last temperature increment had been a positive one), TSTEP is divided in half and its sign changed. TSTEP is then added to TCAN. If TCAN is vanishingly close to 0 C, it is reset to that value. The iteration counter NITER and the flag NUMIT are each incremented by one. Finally, if $\text{NUMIT} > 0$, the iteration cycle is repeated from line 400 on.

If $\text{ITC} = 2$, the calculations for the Newton-Raphson method of iteration in loop 575 are performed, over each of the modelled areas for which $\text{ITER} = 1$. As outlined above, in this approach the value x_{n+1} used at each iteration step

is obtained from the value x_n at the previous step as follows:

$$x_{n+1} = x_n - f(x_n)/f'(x_n)$$

Identifying x_n with TCAN and $f(x_n)$ with the surface energy balance equation, it can be seen that the second term on the right-hand side corresponds to TSTEP; the numerator is equal to RESID and the denominator to the first derivative of the energy balance equation evaluated at TCAN, which in turn is equal to the sum of the derivatives of the individual terms:

$$d(L_{*c})/dT = -8\sigma T_c^3(1 - \chi)$$

$$d(Q_{H,c})/dT = \rho_a c_p 1/r_A + [T_c - T_{a,pot}]d(1/r_A)/dT$$

$$d(Q_{E,c})/dT = L_v \rho_a X_E dq_c/dT + [q_c - q_a]dX_E/dT$$

$$d\Delta Q_{S,c}/dT = C_c/\Delta t$$

The term $d(1/r_A)/dT$ is represented by the variable DCFLXM, which is approximated as the difference between CFLX and its value for the previous iteration, CFLUXM, divided by TSTEP. The term dX_E/dT is represented by the variable DXEVAP, which is approximated as the difference between XEVAP and its value for the previous iteration, XEVAPM, divided by TSTEP. The calculated value of TSTEP obtained from the above calculations is constrained to be between -10 and 5 K to dampen any spurious oscillations, and is then added to TCAN. If the resulting value of TCAN is vanishingly close to 0 C, it is reset to that value. At the end of the calculations the iteration counter NITER and the flag NUMIT are each incremented by one. The values of $T_{a,c}$, $q_{a,c}$ and $T_{ac,v}$ are reset to T_c , q_c and $T_{c,v}$ respectively. Upon exiting the loop, if NUMIT > 0, the iteration cycle is repeated from line 400 on.

After the iteration has been completed, if the Newton-Raphson method has been used, a check is carried out in loop 600 to ascertain whether convergence has not been reached (i.e. whether ITER = -1) for any location. In such cases it is assumed that conditions of near-neutral stability at the surface are the cause of the difficulty in finding a solution. The flags NUMIT and IEVAPC are set to zero, and a trial value of TCAN is calculated using the virtual potential temperature of the air and the canopy specific humidity. If the absolute value of RESID is $> 100 W m^{-2}$, TCAN is set to this trial value. The values of $q_{0,c}$ and the components of the surface energy balance are recalculated as above, except that $\{H,c\}$ and $Q_{\{E,c\}}$ are assumed as a first approximation to be zero. RESID is determined on this basis, and is then assigned to $\{H,c\}$ and $\{E,c\}$. If RESID > 0, $Q_{\{E,c\}}$ is set to this value; otherwise it is equally divided between $Q_{\{H,c\}}$ and $Q_{\{E,c\}}$. The residual is then reset to zero, and $E(0)$ and $\{v,c\}$

After loop 600, calls to DRCOEF or FLXSURFZ are performed to re-evaluate the surface turbulent transfer coefficients for any locations for which the fluxes were modified in the previous loop, i.e. for any locations for which IEVAPC was set to 1. After this a check is performed for unphysical values of the canopy temperature, i.e. for values greater than 100 C or less than -100 C. If such values are encountered, an error message is printed and a call to abort is carried out.

Next a check is carried out to determine whether freezing or melting of intercepted water has occurred over the current time step. If this is the case, adjustments are required to the canopy temperature, the intercepted liquid and frozen water amounts and fractional coverages, and to C_c and $\Delta Q_{S,c}$. In loop 650, if there is liquid water stored on the canopy and the canopy temperature is less than 0 C, the first half of the adjustment to $\Delta Q_{S,c}$ is performed, and the flags ITER and NIT are set to 1. The available energy sink HFREZ is calculated from CHCAP and the difference between TCAN and 0 C, and compared with HCONV, calculated as the energy sink required to freeze all of the liquid water on the canopy. If $HFREZ \leq HCONV$, the amount of water that can be frozen is calculated using the latent heat of melting. The fractional coverages of frozen and liquid water FSNOWC and FRAINCC and their masses SNOCAN and RAICAN are adjusted accordingly, TCAN is set to 0 C, and the amount of energy involved is stored in the diagnostic variable QMELTC. Otherwise all of the intercepted liquid water is converted to frozen water, and the energy available for cooling the canopy is calculated as HCOOL = HFREZ - HCONV. This available energy is applied to decreasing the temperature of the canopy, using the specific heat of the canopy elements, and the amount of energy that was involved in the phase change is stored in the diagnostic variable QMELTC. In both cases q_c and $T_{c,v}$ are recalculated, and at the end of the loop C_c and $\Delta Q_{S,c}$ are re-evaluated.

In loop 675, if there is frozen water stored on the canopy and the canopy temperature is greater than 0 C, the first half of the adjustment to $\Delta Q_{S,c}$ is performed, and the flags ITER and NIT are set to 1. The available energy for melting, HMELT, is calculated from CHCAP and the difference between TCAN and 0 C, and compared with HCONV, calculated as the energy required to melt all of the frozen water on the canopy. If $HMELT \leq HCONV$, the amount of frozen water that can be melted is calculated using the latent heat of melting. The fractional coverages of frozen and liquid water FSNOWC and FRAINCC and their masses SNOCAN and RAICAN are adjusted accordingly, TCAN

is set to 0 C, and the amount of energy involved is stored in the diagnostic variable QMELTC. Otherwise, all of the intercepted frozen water is converted to liquid water, and the energy available for warming the canopy is calculated as $H_{WARM} = H_{MELT} - H_{CONV}$. This available energy is applied to increasing the temperature of the canopy, using the specific heats of the canopy elements, and the amount of energy that was involved in the phase change is stored in the diagnostic variable QMELTC. In both cases q_c and $T_{c,v}$ are recalculated, and at the end of the loop C_c and $\Delta Q_{S,c}$ are re-evaluated.

For the locations over which melting or freezing of water on the canopy has occurred, the surface fluxes must now be recalculated to reflect the modified canopy temperature and humidity. If $NIT > 0$, first DRCOEF or FLXSURFZ is called to re-evaluate the surface turbulent transfer coefficients over all locations where ITER has been set to 1. Loops 700 and 750 repeat the calculations done in loops 475 and 500, to obtain the surface transfer coefficients. Loop 800 repeats the calculations of the surface fluxes done in loop 525.

At the end of the subroutine, some final diagnostic and clean-up calculations are performed. If the evaporation rate from the canopy, EVAPC, is very small, it is added to the residual of the canopy energy balance equation, RESID, and then reset to zero. The overall residual is added to the sensible heat flux from the canopy. The energy balance of the surface underlying the canopy is then re-evaluated to take into account the new value of the canopy longwave radiation. If the surface temperature is close to 0 C, the residual of the equation is assigned to QMELTG, representing the energy associated with melting or freezing of water at the surface; otherwise it is assigned to the ground heat flux. If the water vapour flux is towards the canopy, the water sublimated or condensed is assigned to interception storage: to SNOCAN if $SNOCAN > 0$ (for consistency with the definition of CPHCHC), and to RAICAN otherwise. The diagnostic water vapour flux variables QFCF and QFCL, and the diagnostic change of canopy heat storage HTCC, are updated accordingly, and the canopy heat capacity CHCAP is recalculated; EVAPC is added to the diagnostic variable EVAP and then reset to zero. The net shortwave radiation, outgoing longwave radiation, sensible and latent heat fluxes are calculated for the whole canopy-ground surface ensemble; the evaporation rates are converted to ms^{-1} ; and the iteration counter ITERCT is updated for the level corresponding to the subarea type and the value of NITER. Finally, the fraction of water removed by transpiration from each soil layer is updated according to the fractions determined above on the basis of water availability.

Parameters

<i>isnow</i>	Flag indicating presence or absence of snow
<i>isnoalb</i>	Switch to model snow albedo in two or more wavelength bands
<i>qswnet</i>	Net shortwave radiation at surface [Wm^{-2}]
<i>qlwout</i>	Upwelling longwave radiation at surface [Wm^{-2}] (L)
<i>qtrans</i>	Shortwave radiation transmitted into surface [Wm^{-2}]
<i>qsens</i>	Sensible heat flux from surface [Wm^{-2}](Q_H)
<i>qevap</i>	Latent heat flux from surface [Wm^{-2}](Q_E)
<i>evap</i>	Evaporation rate at surface [$kgm^{-2}s^{-1}$]($E(0)$)
<i>tzero</i>	Temperature at surface [K]($T(0)$)
<i>qzero</i>	Specific humidity at surface [$kgkg^{-1}$]($q(0)$)
<i>gzero</i>	Heat flux into surface [Wm^{-2}]($G(0)$)
<i>qmelt</i>	Heat available for melting snow or freezing water at the surface [Wm^{-2}]
<i>cdh</i>	Surface drag coefficient for heat [$](C_{DH})$
<i>cdm</i>	Surface drag coefficient for momentum []
<i>rib</i>	Bulk Richardson number at surface []
<i>cflux</i>	Product of surface drag coefficient and wind speed [ms^{-1}]
<i>ftemp</i>	Product of surface-air temperature gradient, drag coefficient and wind speed [Kms^{-1}]
<i>fvap</i>	Product of surface-air humidity gradient, drag coefficient and wind speed [$kgkg^{-1}ms^{-1}$]
<i>ilmo</i>	Inverse of Monin-Obukhov roughness length ($m - 1$)
<i>ue</i>	Friction velocity of air [ms^{-1}]
<i>h</i>	Height of the atmospheric boundary layer [m]
<i>zpond</i>	Depth of ponded water on surface [m]
<i>fi</i>	Fractional coverage of subarea in question on modelled area []
<i>qlwin</i>	Downwelling longwave radiation at bottom of atmosphere [Wm^{-2}]
<i>tpota</i>	Potential temperature of air at reference height [K]($T_{a,pot}$)
<i>qa</i>	Specific humidity at reference height [$kgkg^{-1}$](q_a)
<i>va</i>	Wind speed at reference height [ms^{-1}](v_a)
<i>padry</i>	Partial pressure of dry air [Pa](p_{dry})
<i>rhoair</i>	Density of air [kgm^{-3}](ρ_a)
<i>alvisg</i>	Visible albedo of ground surface []
<i>alnirg</i>	Near-IR albedo of ground surface []
<i>crib</i>	Richardson number coefficient [K^{-1}]
<i>cphch</i>	Latent heat of vaporization at surface [Jkg^{-1}]
<i>cevap</i>	Soil evaporation efficiency coefficient [$](\beta)$
<i>tvirta</i>	Virtual potential temperature of air at reference height [K]
<i>zosclh</i>	Ratio of roughness length for heat to reference height for temperature and humidity []
<i>zosclm</i>	Ratio of roughness length for momentum to reference height for wind speed []
<i>zrslfh</i>	Difference between reference height for temperature and humidity and height at which extrapolated wind speed goes to zero [m]
<i>zrslfm</i>	Difference between reference height for wind speed and height at which extrapolated wind speed goes to zero [m]
<i>zoh</i>	Surface roughness length for heat [m]
<i>zom</i>	Surface roughness length for momentum [m]
<i>gconst</i>	Intercept used in equation relating surface heat flux to surface temperature [Wm^{-2}]

<i>gcoeff</i>	Multiplier used in equation relating surface heat flux to surface temperature [$Wm^{-2}K^{-1}$]
<i>tstart</i>	Starting point for surface temperature iteration [K]
<i>fcor</i>	Coriolis parameter [s^{-1}]
<i>pcpr</i>	Surface precipitation rate [$kgm^{-2}s^{-1}$]
<i>rhosno</i>	Density of snow [kgm^{-3}]
<i>zsnow</i>	Depth of snow pack [m] (z_s)
<i>thliq</i>	Volumetric liquid water content of soil layers [m^3m^{-3}]
<i>thlmin</i>	Residual soil liquid water content remaining after freezing or evaporation [m^3m^{-3}]
<i>delzw</i>	Permeable thickness of soil layer [m]
<i>trsnowg</i>	Short-wave transmissivity of snow pack over bare ground []
<i>alsno</i>	Albedo of snow in each modelled wavelength band []
<i>fssb</i>	Total solar radiation in each modelled wavelength band [Wm^{-2}]
<i>iwater</i>	Flag indicating condition of surface (dry, water-covered or snow-covered)
<i>ievap</i>	Flag indicating whether surface evaporation is occurring or not
<i>iterct</i>	Counter of number of iterations required to solve energy balance for four subareas
<i>isand</i>	Sand content flag

For the surface temperature iteration, two alternative schemes are offered: the bisection method (selected if the flag ITG = 1) and the Newton-Raphson method (selected if ITG = 2). In the first case, the maximum number of iterations ITERMX is set to 50, and in the second case it is set to 5. An optional windless transfer coefficient EZERO is available, which can be used, following the recommendations of Brown et al. (2006) [Brown2006-ec], to prevent the sensible heat flux over snow packs from becoming vanishingly small under highly stable conditions. Currently, EZERO is set to zero.

In the next section, calculations of surface net and transmitted shortwave radiation are done depending on whether a snow pack is present (ISNOW=1) and whether the incoming shortwave radiation is being supplied in two bands (one visible and one near-IR, ISNOALB=0) or four bands (one visible and three near-IR, ISNOALB=1). For each band the net shortwave radiation is calculated as the incoming radiation multiplied by one minus the appropriate albedo. If there is no snow present the shortwave transmissivity at the surface is set to zero and the absorbed visible radiation is calculated from the first radiation band. If ISNOALB=0 the absorbed near-IR radiation is calculated from the second band and if ISNOALB=1 it is calculated from the sum of the second to fourth bands. The total net shortwave radiation QSWNET is then evaluated. If a snow pack is present, then if ISNOALB=0 the calculations are done separately for the visible and near-IR bands; if ISNOALB=1, they are done separately over the four wavelength bands. The transmissivity is calculated as an average value for ISNOALB=0, and separately for the four wavelength ranges for ISNOALB=1. The net shortwave radiation at the surface is obtained from the sum of the net values in each wavelength band, corrected for the respective loss by transmission into the surface.

The 100 continuation line marks the beginning of the surface temperature iteration sequence. First the flags NIT (indicating that there are still locations at the beginning of the current iteration step for which the surface temperature has not yet been found) and NUMIT (indicating that there are still locations at the end of the current iteration step for which the surface temperature has not yet been found) are set to zero. Loop 150 is then performed over the set of modelled areas. If ITER=1, NIT is incremented by one, and the initial value of the surface transfer coefficient CFLUXM for this iteration pass is set to its value from the previous pass. The virtual temperature at the surface, $T(0)_v$, is obtained using the standard expression (see documentation for subroutine CLASST):

$$T(0)_v = T(0)[1 + 0.61q(0)]$$

where $T(0)$ is the surface temperature and $q(0)$ is the specific humidity at the surface. The surface humidity can be obtained from the saturated specific humidity $q(0)_{sat}$ by making use of the definition of the surface evaporation efficiency β :

$$\beta = [q(0) - q_a] / [q(0)_{sat} - q_a]$$

where q_a is the specific humidity of the air at the reference height. This expression is inverted to obtain an expression for $q(0)$. The saturated specific humidity $q(0)_{sat}$ is determined from the mixing ratio at saturation, $w(0)_{sat}$:

$$q(0)_{sat} = w(0)_{sat} / [1 + w(0)_{sat}]$$

The saturation mixing ratio is a function of the saturation vapour pressure $e(0)_{sat}$ at the surface:

$$w(0)_{sat} = 0.622e(0)_{sat} / (p_{dry})$$

where p_{dry} is the partial pressure of dry air. A standard empirical equation for the saturation vapour pressure dependence on the temperature T is used:

$$e_{sat} = 611.0 \exp[17.269(T \sim T_f)/(T \sim 35.86)] T \geq T_f \quad e_{sat} = 611.0 \exp[21.874(T \sim T_f)/(T \sim 7.66)] T < T_f$$

where T_f is the freezing point. If there is a snow cover or ponded water present on the surface ($IWATER > 0$), the surface evaporation efficiency $EVBETA$ is set to 1 and $q(0)$ is set to $q(0)_{sat}$. Otherwise $EVBETA$ is set to $CEVAP$, the value obtained in subroutine $TPREP$ on the basis of ambient conditions, and $q(0)$ is calculated as above. If $q(0) > q_a$ and the evaporation flag $IEVAP$ has been set to zero, $EVBETA$ is reset to zero and $q(0)$ is reset to q_a . Finally, $T(0)_v$ is determined using the equation above.

If $NIT > 0$, a subroutine is called to evaluate the stability- corrected surface drag coefficients for heat and momentum. The subroutine selection is made on the basis of the flag $ISLFD$. If $ISLFD=1$, indicating that the calculations are to be consistent with CCCma conventions, subroutine $DRCOEF$ is called; if $ISLFD=2$, indicating that the calculations are to be consistent with RPN conventions, subroutine $FLXSURFZ$ is called.

In loop 175, the terms of the surface energy balance are evaluated. The energy balance equation is written as:

$$K_* + L_* - Q_H \sim Q_E \sim G(0) = 0$$

where K_* is the net shortwave radiation, L_* is the net longwave radiation, Q_H is the sensible heat flux, Q_E is the latent heat flux, and $G(0)$ is the conduction into the surface. K_* was evaluated earlier in loop 50. L_* is obtained as the difference between the downwelling radiation $L \downarrow$ and the upwelling radiation $L \uparrow$, which in turn is determined using the Stefan- Boltzmann equation:

$$L \uparrow = \sigma T(0)^4$$

where σ is the Stefan-Boltzmann constant. (It is assumed that natural surfaces, because of their radiative complexity, act as effective black bodies, so that their emissivity can be taken to be 1.) The sensible heat flux is given by

$$Q_H = [\rho_a c_p C_{DH} v_a + \epsilon_0] [T(0) \sim T_{a,pot}]$$

where ρ_a is the density of the air, c_p is its specific heat, C_{DH} is the surface drag coefficient for heat, and v_a and $T_{a,pot}$ are the wind speed and potential temperature respectively at the reference height. (Note in the code that the variable $CFLUX$, evaluated in subroutine $DRCOEF$ or $FLXSURFZ$, represents the product of C_{DH} and v_a .) The windless transfer coefficient ϵ_0 , evaluated at the beginning of the subroutine, is used only under stable conditions, i.e. if $T(0) < T_{a,pot}$. The evaporation rate at the surface, $E(0)$, is calculated as

$$E(0) = \rho_a C_{DH} v_a [Q(0) \sim q_a]$$

The evaporation rate is constrained to be less than or equal to the maximum rate evaluated earlier in the subroutine. Q_E is obtained by multiplying $E(0)$ by the latent heat of vaporization at the surface. The ground heat flux $G(0)$ is determined as a linear function of $T(0)$ (see documentation for subroutines $TNPREP$ and $TSPREP$). It can be seen that each of the terms of the surface energy balance is a function of a single unknown, $T(0)$ or $TZERO$. The residual $RESID$ of the energy balance is now evaluated on the basis of the current estimation for $TZERO$. If the absolute value of $RESID$ is less than $5.0 W m^{-2}$, or if the absolute value of the iteration step $TSTEP$ most recently used is less than 0.01 K, the surface temperature is deemed to have been found and $ITER$ is set to 0. If the iteration counter $NITER$ is equal to the maximum number and $ITER$ is still 1, $ITER$ is set to -1.

In the following section, the iteration sequence is moved ahead a step. If $ITG = 1$, then if $NIT > 0$ and if $ITER$ for the array element in question is 1, the calculations for the bisection method of solution are performed. If $NITER = 1$ (indicating that this is the first step in the iteration), then if $RESID > 0$ (indicating that the current value for $TZERO$ had undershot the correct value), $TZERO$ is incremented by 1 K; otherwise it is decremented by 1 K. If this is not the first step in the iteration, then if $RESID > 0$ and $TSTEP < 0$ (indicating that $TZERO$ has undershot the correct value and the last temperature increment had been a negative one) or if $RESID < 0$ and $TSTEP > 0$ (indicating that $TZERO$ has overshot the correct value and the last temperature increment had been a positive one), $TSTEP$ is divided in half and its sign changed. $TSTEP$ is then added to $TZERO$. The iteration counter $NITER$ and the flag $NUMIT$ are each incremented by one. The next loop contains an optional set of print statements that are executed if $ITER=-1$, that is if a solution for the surface temperature has not been found within the prescribed maximum number of iteration steps. Finally, if $NUMIT > 0$, the iteration cycle is repeated from line 100 on.

If $ITG = 2$, then if $NIT > 0$ and if $ITER$ for the array element in question is 1, the calculations for the Newton-Raphson method of iteration are performed. In this approach, the value x_{n+1} used at each iteration step is obtained from the value x_n at the previous step as follows:

$$x_{n+1} = x_n \sim f(x_n) / f'(x_n)$$

Identifying x_n with $TZERO$ and $f(x_n)$ with the surface energy balance equation, it can be seen that the second term on the right-hand side corresponds to $TSTEP$; the numerator is equal to $RESID$ and the denominator to the first

derivative of the energy balance equation evaluated at TZERO, which in turn is equal to the sum of the derivatives of the individual terms:

$$d(L \uparrow)/dT = -4\sigma T(0)^3$$

$$d(Q_H)/dT = \rho_a c_p C_{DH} v_a + [T(0) \sim T_{a,pot}] d(C_{DH} v_a)/dT$$

$$d(Q_E)/dT = L_v \rho_a C_{DH} v_a dq(0)/dT + [q(0) \sim q_a] d(C_{DH} v_a)/dT$$

and $dG(0)/dT$ is equal to the coefficient multiplying TZERO in the equation for $G(0)$. (L_v is the latent heat of vaporization at the surface.) At the end of the calculations the iteration counter NITER and the flag NUMIT are each incremented by one, and upon exiting the loop, if NUMIT > 0, the iteration cycle is repeated from line 100 on.

After the iteration has been completed, NUMIT is reset to zero and a check is carried out to ascertain whether convergence has not been reached (i.e. whether ITER = -1) for any location. In such cases it is assumed that conditions of near-neutral stability at the surface are the cause of the difficulty in finding a solution. A trial value of TZERO is calculated using the virtual potential temperature of the air. If RESID > $50 W m^{-2}$, TZERO is set to this trial value. The values of $q(0)$ and the components of the surface energy balance are recalculated as above, except that Q_H and Q_E are assumed as a first approximation to be zero. RESID is determined on this basis. If RESID is positive, it is assigned to Q_E ; otherwise RESID is divided equally between Q_H and Q_E , except in the case of an absolutely dry surface, in which case Q_E is set to zero and Q_H to RESID. RESID is reset to zero, $E(0)$ is obtained from Q_E , and $T(0)_v$ is recalculated. The flag JEVAP for the location is set to 1, and NUMIT is incremented by 1. If NUMIT > 0 at the end of this loop, DRCOEF or FLXSURF are called again, and their calculations are performed for any location where JEVAP is 1, to ensure consistency with the new surface temperature and humidity.

At this point a check is performed for unphysical values of the surface temperature, i.e. for values greater than 100 C or less than -250 C. If such values are encountered, an error message is printed and a call to abort is carried out.

Finally, a check is performed to ensure that TZERO is not less than 0 C if ponded water is present on the surface (IWATER = 1) or greater than 0 C if snow is present on the surface (IWATER = 2), or greater than zero if the surface is an ice sheet (ISAND = -4). If any of these cases is true, TZERO is reset to the freezing point, and $q(0)$ and $T(0)_v$ are recalculated. DRCOEF or FLXSURFZ are called, and their calculations are performed for all locations meeting these criteria. The components of the surface energy balance are recalculated; the residual amount is assigned to the energy associated with phase change of water at the surface, QMELT, and RESID is set to zero. If QMELT < 0, i.e. if there is freezing taking place, the evaporation flux QEVP is added to it and then reset to zero (since if ponded water is freezing, it is unavailable for evaporation).

In the last half of the loop, some final adjustments are made to a few variables. If the evaporation flux is vanishingly small, it is added to RESID and reset to zero. If an anomalous case has arisen in which QMELT < 0 over a snow-covered surface or QMELT > 0 over a snow-free surface, QMELT is added to the heat flux into the surface and then reset to zero. Any remaining residual flux is added to Q_H . The shortwave radiation transmitted into the surface is added back to the net shortwave radiation for diagnostic purposes. The surface vapour flux is converted into units of ms^{-1} . Lastly, the iteration counter ITERCT is updated for the level corresponding to the subarea type and the value of NITER.

<i>tcsnow</i>	Thermal conductivity of snow $[Wm^{-1}K^{-1}]$
<i>hcpsno</i>	Heat capacity of snow $[Jm^{-3}K^{-1}](C_s)$
<i>qtrans</i>	Shortwave radiation transmitted through the snow pack $[Wm^{-2}]$
<i>gconst</i>	Intercept used in equation relating snow surface heat flux to snow surface temperature $[Wm^{-2}]$
<i>gcoeff</i>	Multiplier used in equation relating snow surface heat flux to snow surface temperature $[Wm^{-2}K^{-1}]$
<i>fi</i>	Fractional coverage of subarea in question on modelled area $[(X_i)]$
<i>gconsts</i>	Intercept used in equation relating snow surface heat flux to snow surface temperature $[Wm^{-2}]$
<i>gcoeffs</i>	Multiplier used in equation relating snow surface heat flux to snow surface temperature $[Wm^{-2}K^{-1}]$
<i>tbar</i>	Temperatures of soil layers, averaged over modelled area [K]
<i>delz</i>	Overall thickness of soil layer [m]

In the 100 loop, the heat flux into the snow surface (without adjustments that may have been applied relating to partitioning of the residual of the surface energy balance among the surface flux terms) is calculated from the snow surface temperature *TSURF*, using the *GCOEFFS* and *GCONSTS* terms (see documentation of subroutine *TSPREP*). The temperature at the bottom of the snow pack, *TSNBOT*, is then calculated. Currently *TSNBOT* is determined as a simple average of the temperatures of the snow and the first soil layer, weighted according to their respective depths (and constrained to be ≤ 0 C), but this is under review. The heat flux into the soil surface is then evaluated from *TSNBOT* and the *GCOEFF* and *GCONST* terms (see documentation of subroutine *TNPREP*). If the energy to be applied to the melting of snow, *QMELTG*, is negative (indicating an energy sink), *QMELTG* is added to the heat flux into the ground, *GZERO*, and reset to zero. The temperature of the snow pack is then stepped forward using the heat fluxes at the top and bottom of the snow pack, $G(0)$ and $G(\Delta z_s)$:

$$\Delta T_s = [G(0) - G(\Delta z_s)]\Delta t / (C_s \Delta z_s)$$

where C_s is the snow heat capacity, Δt the time step and Δz_s the snow depth. If the new snow temperature is greater than zero, the excess amount of heat is calculated and added to *QMELTG* and subtracted from *GSNOW*, and *TSNOW* is reset to 0 C. Finally, the shortwave radiation transmitted through the snow pack, *QTRANS*, is added to *GZERO*.

In the 200 loop, since liquid water is assumed only to exist in the snow pack if it is at 0 C, a check is carried out to determine whether the liquid water content *WSNOW* > 0 at the same time as the snow temperature *TSNOW* < 0 . If so, the change of internal energy I_s of the snow pack as a result of this phase change is calculated as the difference in I_s between the beginning and end of the loop:

$$\Delta I_s = X_i \Delta [C_s T_s] / \Delta t$$

where X_i represents the fractional coverage of the subarea under consideration relative to the modelled area. The total energy sink HADD available to freeze liquid water in the snow pack is calculated from TSNOW, and the amount of energy HCONV required to freeze all the available water is calculated from WSNOW. If $HADD < HCONV$, only part of WSNOW is frozen; this amount WFREZ is calculated from HADD and subtracted from WSNOW, the snow temperature is reset to 0 C, the frozen water is used to update the snow density, and the snow heat capacity is recalculated:

$$C_s = C_i [\rho_s / \rho_i] + C_w w_s / [\rho_w \Delta z_s]$$

where C_i and C_w are the heat capacities of ice and water respectively, w_s is the snow water content and ρ_s , ρ_i and ρ_w are the densities of snow, ice and water respectively. If $HADD > HCONV$, the available energy sink is sufficient to freeze all of WSNOW. HADD is recalculated as $HADD - HCONV$, WFREZ is set to WSNOW and added to the snow density, WSNOW is set to zero, the snow heat capacity is recalculated and HADD is used to determine a new value of TSNOW. Finally, WFREZ is used to update the diagnostic variables HMFN describing phase changes of water in the snow pack, and the change in internal energy HTCS.

Calculate coefficients for solution of snow pack heat conduction.

Functions/Subroutines

- subroutine [tsprep](#) (GCOEFFS, GCONSTS, CPHCHG, IWATER, FI, ZSNOW, TSNOW, TCSNOW, ILG, IL1, IL2, JL)

6.71.1 Detailed Description

Calculate coefficients for solution of snow pack heat conduction.

6.71.2 Function/Subroutine Documentation

6.71.2.1 subroutine `tsprep` (real, dimension(ilg) *GCOEFFS*, real, dimension(ilg) *GCONSTS*, real, dimension(ilg) *CPHCHG*, integer, dimension(ilg) *IWATER*, real, dimension (ilg) *FI*, real, dimension (ilg) *ZSNOW*, real, dimension (ilg) *TSNOW*, real, dimension(ilg) *TCSNOW*, integer *ILG*, integer *IL1*, integer *IL2*, integer *JL*)

Parameters

<i>gcoeffs</i>	Multiplier used in equation relating snow surface heat flux to snow surface temperature [$W m^{-2} K^{-1}$]
<i>gconsts</i>	Intercept used in equation relating snow surface heat flux to snow surface temperature [$W m^{-2}$]
<i>cphchg</i>	Latent heat of sublimation [$J kg^{-1}$]
<i>iwater</i>	Flag indicating condition of surface (dry, water-covered or snow-covered)
<i>fi</i>	Fractional coverage of subarea in question on modelled area []
<i>zsnow</i>	Depth of snow pack [m](Δz_s)
<i>tsnow</i>	Snowpack temperature [K]($T_s(\Delta z_s)$)
<i>tcsnow</i>	Thermal conductivity of snow [$W m^{-1} K^{-1}$]

In this subroutine, coefficients are derived for an equation relating the heat flux at the snow surface to the snow surface temperature. It is assumed that the variation of temperature T with depth z in the snow pack can be modelled by using a quadratic equation:

$$T(z) = (1/2)az^2 + bz + c$$

By substituting 0 for z in the above equation and in the expressions for its first and second derivatives, it can be shown that $a = T''(0)$, $b = T'(0)$, and $c = T(0)$. The term $T''(0)$ can be evaluated from the expression for the first derivative evaluated at the bottom of the snow pack, $T'(\Delta z_s)$:

$$T'''(0) = [T'(\Delta z_s) - T'(0)]/\Delta z_s$$

The temperature gradient $T'(0)$ at the snow surface is related to the surface heat flux $G(0)$ by the snow thermal conductivity λ_s :

$$G(0) = -\lambda_s T'(0)$$

The average snow temperature, $T_s(\Delta z_s)$, can be obtained by integrating the resulting equation for $T(z)$ between 0 and Δz_s . Making use of all of the above expressions, and assuming as a first approximation that the heat flux at the bottom of the snow pack is zero, a linear equation can be derived relating $G(0)$ to $T(0)$:

$$G(0) = 3\lambda_s/\Delta z_s [T(0) - T_s(\Delta z_s)]$$

Just four calculations are performed in this subroutine. The slope and intercept of the $G(0)$ vs. $T(0)$ relation, G_{\leftarrow} COEFF and GCONST, are evaluated as $3\lambda_s/\Delta z_s$ and $-3\lambda_s T_s(\Delta z_s)/\Delta z_s$ respectively; the flag IWATER is set to 2, indicating a snow surface; and the latent heat of vaporization at the surface, CPHCHG, is set to the value for sublimation (by adding the latent heat of melting to the latent heat of vaporization).

- CALCULATE COEFFICIENTS.

Canadian Terrestrial Ecosystem Model (CTEM) Stem And Root Turnover Subroutine.

Functions/Subroutines

- subroutine [turnover](#) (stemmass, rootmass, lfstatus, ailcg, il1, il2, leapnow, sort, nol2pfts, fcancmx,

6.72.1 Detailed Description

Canadian Terrestrial Ecosystem Model (CTEM) Stem And Root Turnover Subroutine.

The turnover of stem and root components is modelled via their PFT-dependent specified lifetimes. The litter generation ($kg\ C\ m^{-2}\ day^{-1}$) associated with turnover of stem (D_S) and root (D_R) components is calculated based on the amount of biomass in the respective components ($C_S, C_R; kg\ C\ m^{-2}$) and their respective turnover timescales (τ_S and $\tau_R; yr$; see also [ctem_params.f90](#)) as

$$D_i = C_i \left[1 - \exp \left(-\frac{1}{365 \tau_i} \right) \right], \quad i = S, R.$$

6.72.2 Function/Subroutine Documentation

6.72.2.1 subroutine turnover (real, dimension(ilg,icc) *stemmass*, real, dimension(ilg,icc) *rootmass*, integer, dimension(ilg,icc) *lfstatus*, real, dimension(ilg,icc) *ailcg*, integer *il1*, integer *il2*, logical *leapnow*, integer, dimension(icc) *sort*, integer, dimension(ican) *nol2pfts*, real, dimension(ilg,icc) *fcancmx*)

Parameters

<i>il1</i>	<i>il1=1</i>
------------	--------------

<i>il2</i>	il2=ilg
<i>lfstatus</i>	leaf status. an integer indicating if leaves are in "max. growth", "normal growth", "fall/harvest", or "no leaves" mode. see phenolgy subroutine for more details.
<i>leapnow</i>	true if this year is a leap year. Only used if the switch 'leap' is true.
<i>sort</i>	index for correspondence between 9 ctem pfts and size 12 of parameter vectors
<i>nol2pfts</i>	number of level 2 ctem pfts
<i>stemmass</i>	stem mass for each of the 9 ctem pfts, kgc/m^2
<i>rootmass</i>	root mass for each of the 9 ctem pfts, kgc/m^2
<i>ailcg</i>	green or live lai
<i>fcancmx</i>	max. fractional coverage of ctem's 9 pfts, but this can be modified by land-use change, and competition between pfts

Constants and parameters are located in [ctem_params.f90](#)

initialize required arrays to zero

initialization ends

calculate normal stem and root litter using the amount of stem and root biomass and their turnover time scales.

if crops are in harvest mode then we start harvesting stem as well. if stem has already been harvested then we set the stem harvest loss equal to zero. the roots of the crop die in a similar way.

stem/root harvest/death for crops

add stem and root litter from all sources

Check for freezing or thawing of liquid or frozen water in the soil layers, and adjust layer temperatures and water stores accordingly.

Functions/Subroutines

- subroutine [twcalc](#) (TBAR, THLIQ, THICE, HCP, TBARW, HMFG, HTC, FI, EVAP, THPOR, THLMIN, HCPS, DELZW, DELZZ, ISAND, IG, ILG, IL1, IL2, JL)

6.73.1 Detailed Description

Check for freezing or thawing of liquid or frozen water in the soil layers, and adjust layer temperatures and water stores accordingly.

6.73.2 Function/Subroutine Documentation

- 6.73.2.1 subroutine twcalc (real, dimension (ilg,ig) *TBAR*, real, dimension (ilg,ig) *THLIQ*, real, dimension (ilg,ig) *THICE*, real, dimension (ilg,ig) *HCP*, real, dimension (ilg,ig) *TBARW*, real, dimension (ilg,ig) *HMFG*, real, dimension (ilg,ig) *HTC*, real, dimension (ilg) *FI*, real, dimension (ilg) *EVAP*, real, dimension (ilg,ig) *THPOR*, real, dimension (ilg,ig) *THLMIN*, real, dimension (ilg,ig) *HCPS*, real, dimension (ilg,ig) *DELZW*, real, dimension (ilg,ig) *DELZZ*, integer, dimension (ilg,ig) *ISAND*, integer *IG*, integer *ILG*, integer *IL1*, integer *IL2*, integer *JL*)

Parameters

<i>tbar</i>	Temperature of soil layer $[C](T_g)$
<i>thliq</i>	Volumetric liquid water content of soil layer $[m^3m^{-3}](\theta_l)$
<i>thice</i>	Volumetric frozen water content of soil layer $[m^3m^{-3}](\theta_i)$
<i>hcp</i>	Heat capacity of soil layer $[Jm^{-3}K^{-1}](C_g)$
<i>tbarw</i>	Temperature of water in soil layer $[C]$
<i>hmfg</i>	Energy associated with freezing or thawing of water in soil layer $[Wm^{-2}]$
<i>htc</i>	Internal energy change of soil layer due to conduction and/or change in mass $[Wm^{-2}](I_g)$
<i>fi</i>	Fractional coverage of subarea in question on modelled area $[](X_i)$
<i>evap</i>	Calculated evaporation rate from soil surface $[ms^{-1}]$
<i>thpor</i>	Pore volume in soil layer $[mm](\theta_p)$
<i>thlmin</i>	Residual soil liquid water content remaining after freezing or evaporation $[m^3m^{-3}](\theta_r)$
<i>hcps</i>	Heat capacity of soil material $[Jm^{-3}K^{-1}](C_m)$
<i>delzw</i>	Permeable thickness of soil layer $[m](\Delta z_{g,w})$
<i>delzz</i>	Soil layer thicknesses to bottom of permeable depth for standard three-layer configuration, or to bottom of thermal depth for multiple layers $[m](\Delta z_{g,z})$
<i>isand</i>	Sand content flag

The adjustments of soil layer temperature and water content in this routine are done over the whole soil profile in the case of multiple soil layers (see the section on assignment of background data), but only to the bottom of the permeable depth in the case of the standard three-layer configuration (0.10, 0.25 and 3.75 m). This is because if the permeable depth lies within the thick third soil layer, it is recognized as desirable to apply the temperature changes only to that upper part of the layer in which the phase change is occurring, in order to avoid systematic damping of the temperature response of the layer. Thus the local array DELZZ (set in subroutine WPREP) is used here instead of DELZ when referring to the total thermal thickness of the soil layer, where DELZZ=DELZW for the third soil layer when the three-layer configuration is being used, but DELZZ=DELZ for all other cases.

The heat capacity C_g of the permeable part $\Delta z_{g,w}$ of the soil layer under consideration is calculated here and in various other places in the subroutine as the weighted average of the heat capacities of the liquid water content θ_l , the frozen water content θ_i , and the soil material (taken to apply to the volume fraction not occupied by the pore volume θ_p). The heat capacity of air in the pores is neglected:

$$C_g = C_w\theta_l + C_i\theta_i + C_m(1 - \theta_p)$$

Over the impermeable portion of the layer, the heat capacity of rock C_r is assumed to apply. Thus an effective heat capacity $C_{g,e}$ (in units of $Jm^{-2}K^{-1}$) over the soil layer in question, $\Delta z_{g,z}$, can be calculated as:

$$C_{g,e} = C_g\Delta z_{g,w} + C_r(\Delta z_{g,z} - \Delta z_{g,w})$$

The change of internal energy I in the soil layers as a result of freezing and thawing is calculated as the difference in I between the beginning and end of the subroutine:

$$\Delta I_j = X_i\Delta(C_{g,e}T_g)/\Delta t$$

where T_g is the temperature of the layer, Δt the length of the time step, and X_i the fractional coverage of the subarea under consideration relative to the modelled area.

If the soil layer temperature is less than 0 C and the volumetric liquid water content θ_l of the layer is greater than the residual water content θ_f , the water content THFREZ that can be frozen by the available energy sink is calculated from C_e and T_g . The volumetric water content THEVAP of the first layer that is required to satisfy the surface evaporative flux is determined. For each layer, if THLIQ is found to exceed THLMIN + THEVAP, THFREZ is compared to the available water. If $THFREZ \leq THLIQ - THLMIN - THEVAP$, all of the available energy sink is used to freeze part of the liquid water content in the permeable part of the soil layer, the amount of energy involved is subtracted from HTC and added to HMFG, C_g is recalculated and the layer temperature is set to 0 C. Otherwise, all of the liquid water content of the layer above THLMIN + THEVAP is converted to frozen water, and HMFG and HTC are recalculated to reflect this. Then C_g is recomputed, and the remaining energy sink is applied to decreasing the temperature of the soil layer (both the permeable and impermeable portions) using C_e .

If the soil layer temperature is greater than 0 C and the volumetric ice content θ_i of the layer is greater than zero, the ice content THMELT that can be melted by the available energy is calculated from C_e and T_g . For each layer, if $THMELT \leq THICE$, all of the available energy is used to melt part of the frozen water content of the permeable part of the layer, the amount of energy involved is subtracted from HTC and added to HMFG, C_g is recalculated and the layer temperature is set to 0 C. Otherwise, all of the frozen water content of the layer is converted to liquid water,

and HMFG and HTC are recalculated to reflect this. Then C_g is recomputed, and the remaining energy is applied to increasing the temperature of the soil layer (both the permeable and impermeable portions) using C_e .

In the final cleanup, the internal energy calculations for this subroutine are completed, and the first half of a new set of internal energy calculations is done to span the subroutines treating ground water movement, which will be completed in subroutine TMCALC. Lastly, TBARW, the liquid water temperature of each soil layer, is assigned using TBAR.

Parameters

<i>thliqx</i>	Volumetric liquid water content of soil layer [m^3m^{-3}]
<i>thicex</i>	Volumetric frozen water content of soil layer [m^3m^{-3}]
<i>tbarwx</i>	Temperature of water in soil layer [C]
<i>zpond</i>	Depth of ponded water [m]
<i>tpond</i>	Temperature of ponded water [C]
<i>basflw</i>	Base flow from bottom of soil column [kgm^{-2}]

<i>tbasfl</i>	Temperature of base flow from bottom of soil column [K]
<i>runoff</i>	Total runoff from soil column [m]
<i>trunof</i>	Temperature of total runoff from soil column [K]
<i>wmove</i>	Water movement matrix [m^3m^{-2}]
<i>tmove</i>	Temperature matrix associated with ground water movement [C]
<i>thlinf</i>	Volumetric liquid water content behind the wetting front [m^3m^{-3}]
<i>fi</i>	Fractional coverage of subarea in question on modelled area []
<i>trmdr</i>	Time remaining in current time step [s]
<i>delzx</i>	Permeable depth of soil layer [m]

At levels in the soil profile lower than the bottom of the wetting front, redistribution of soil liquid water proceeds in response to normal gravity and suction forces. Subroutine GRDRAN is called to calculate these redistributions. The time period TUSED that is passed to GRDRAN is set in the 100 loop to the time period over which infiltration was occurring during the current time step, except if the wetting front has passed the bottom of the lowest soil layer, in which case TUSED is set to zero (since the flows calculated by GRDRAN are not required). GRDRAN is called using dummy variables THLDUM, THIDUM and TDUMW, which are set in loop 125 to the liquid water content, the frozen water content and the water temperature of the soil layers respectively.

After GRDRAN has been called, the maximum value of the water movement index NINF is set to the number of soil layers plus 1. The values in the matrix ZRMDR, representing for each soil layer the depth that has not been affected by infiltration, are initialized to the soil permeable layer thicknesses DELZX. The water flows FDT coming out of GRDRAN are set to zero at the soil layer interfaces above the wetting front. For the layer containing the wetting front, if the flow at the bottom of the layer is upward, it is set to zero (to avoid possible overflows in liquid water content).

The values in the three-dimensional matrix ZMAT are initialized to zero. This matrix contains the depth of each soil layer J (including the dummy soil layer below the lowest layer) that is filled by water from level K in the water movement matrix WMOVE. In WMOVE, the first level contains the amount of water that has infiltrated at the surface during the time period in question, and each successive level K contains the amount of water in soil layer K-1 that has been displaced during the infiltration, down to the soil layer containing the wetting front. Thus, the number of levels in WMOVE that are used in the current infiltration calculations, NINF, is equal to LZF+1, where LZF is the index of the soil layer containing the wetting front; or to IGP1, the number of soil layers IG plus 1, if LZF is greater than IG, i.e. if the wetting front has penetrated below the bottom of the lowest soil layer into the underlying dummy layer. In the 400 loop, starting at the top of the soil profile, an attempt is made to assign each layer of WMOVE, converted into a depth by using the volumetric water content THLINF behind the wetting front for the soil layer, in turn to the K,J level of ZMAT. If the calculated value of ZMAT is greater than the available depth ZRMDR of the layer, ZMAT is set to ZRMDR, WMOVE is decremented by ZRMDR converted back to a water amount, and ZRMDR is set to zero. Otherwise the calculated value of ZMAT is accepted, ZRMDR is decremented by ZMAT, and WMOVE is set to zero. At the end of these calculations, any remaining residual amounts in the WMOVE matrix are assigned to ponded water, and the ponded water temperature is updated accordingly.

As a result of the above processes, the liquid water content and temperature of each soil layer (excluding the bottom, dummy layer) will be a combined result of infiltration processes (WADD, TADD), redistribution processes (WDRA, TDRA), and water in the layer that has remained unaffected (WREM, TREM). For each layer, WADD is calculated by summing over the respective ZMAT values corresponding to that layer multiplied by THLINF, and TADD by summing over the ZMAT and THLINF values multiplied by the respective TMOVE values. WREM is obtained as the product of the original water content THLIQX multiplied by ZRMDR, and TREM as the product of the water temperature TBARWX, THLIQX and ZRMDR. For the soil layer containing the wetting front, a check is carried out to determine whether the liquid moisture content resulting from the infiltration and drainage processes, THINFL, is less than the residual liquid moisture content THLMIN. If so, the flow FDT at the bottom of the layer is recalculated as the value required to keep THLIQX at THLMIN. WDRA is obtained from the difference between the water fluxes FDT at the top and bottom of the layer, supplied by GRDRAN, and TDRA is obtained from the water fluxes FDT and their corresponding temperatures TFDT. Finally, THLIQX is calculated as the sum of WADD, WREM and WDRA normalized by DELZX, and TBARWX as the sum of TADD, TREM and TDRA normalized by the product of THLIQX and DELZX.

Lastly, the base flow BASFLW at the bottom of the soil profile and its temperature TBASFL are calculated. If the wetting front is located in the dummy soil layer below the soil profile, BASFLW is obtained by summing over the ZMAT values for the IGP1 level, multiplied by the dummy layer THLINF value and the fractional coverage FI of the modelled subarea. TBASFL is similarly obtained as the weighted average of the original TBASFL and the values of TMOVE corresponding to the ZMAT values. The overall subarea runoff RUNOFF and its temperature TRUNOF

are calculated in the same manner without the FI weightings. Otherwise, the baseflow and total runoff are obtained from the value of FDT at the bottom of the IGDR layer, and their temperatures from the values of TFDT and FDT.

Parameters

<i>wmove</i>	Water movement matrix [m^3m^{-2}]
<i>tmove</i>	Temperature matrix associated with ground water movement [C]
<i>lzf</i>	Index of soil layer in which wetting front is located
<i>ninf</i>	Number of levels involved in water movement
<i>zf</i>	Depth of the wetting front [m]
<i>trmdr</i>	Remainder of time step after unsaturated infiltration ceases [s]
<i>r</i>	Rainfall rate at ground surface [ms^{-1}]
<i>tr</i>	Temperature of rainfall [C]
<i>psif</i>	Soil water suction across the wetting front [m]
<i>grkinf</i>	Hydraulic conductivity of soil behind the wetting front [ms^{-1}]
<i>thlinf</i>	Volumetric liquid water content behind the wetting front [m^3m^{-3}]
<i>thliqx</i>	Volumetric liquid water content of soil layer [m^3m^{-3}]
<i>tbarwx</i>	Temperature of water in soil layer [C]
<i>delzx</i>	Permeable depth of soil layer [m] ($\Delta z_{g,w}$)
<i>zbotx</i>	Depth of bottom of soil layer [m]
<i>ifill</i>	Flag indicating whether unsaturated infiltration is occurring

The infiltration rate F_{inf} under conditions of a constant water supply can be expressed, e.g. in Mein and Larson (1973), as

$$F_{inf} = K_{inf} [(\Psi_f + z_f)/z_f]$$

where K_{inf} is the hydraulic conductivity of the soil behind the wetting front, Ψ_f is the soil moisture suction across the wetting front, and z_f is the depth of the wetting front. It can be seen that F_{inf} decreases with increasing z_f to an asymptotic value of K_{inf} . Thus, if the rainfall rate r is less than K_{inf} , the actual infiltration rate is limited by r , i.e. $F_{inf} = r$. Otherwise, F_{inf} will be equal to R until the right-hand side of the above equation becomes less than r , after which point the above equation applies and ponding of excess water begins on the surface. The depth of the wetting front at this time t_p can be calculated by setting F_{inf} equal to r in the above equation and solving for z_f . This results in:

$$z_f = \Psi_f / [r / K_{inf} - 1]$$

The amount of water added to the soil up to the time of ponding is $t_p r$, or $z_f(\theta_{inf} \sim \theta_l)$, where θ_l and θ_{inf} are respectively the liquid water content of the soil before and after the wetting front has passed. Setting these two equal and solving for t_p results in

$$t_p = z_f(\theta_{inf} \sim \theta_l)/r$$

In the 100 loop, a check is done for each successive soil layer to compare the infiltration rate in the layer with the rainfall rate. If $K_{inf} < R$, a test calculation is performed to determine where the depth of the wetting front would theoretically occur at the ponding time t_p . If the calculated value of z_f is less than the depth of the top of the soil layer, z_f is set to the depth of the top of the layer; if z_f falls within the soil layer, that value of z_f is accepted. In both cases, the index LZF is set to the index of the layer, and the flag IFIND, indicating that z_f has been successfully located, is set to 1. If the infiltration rate in the soil layer is greater than the rainfall rate, z_f is provisionally set to the bottom of the current layer, and LZF to the index of the next layer. IFIND remains zero. If the infiltration rate in the layer is vanishingly small, z_f is set to the depth of the top of the current layer, LZF to the index of the overlying layer, and IFIND to 1.

If LZF is greater than 1, some adjustment to the equation for t_p above is required to account for the fact that the values of θ_{inf} and θ_l in the layer containing the wetting front may differ from those in the overlying layers. The equation for t_p above can be rewritten as

$$t_p = [z_f[\theta_{inf}(z_f) \sim \theta_l(z_f)] + w_{adj}]/r$$

where w_{adj} is calculated as

$$LZF - 1$$

$$w_{adj} = \sum[(\theta_{inf,i} \sim \theta_{l,i}) \sim (\theta_{inf}(z_f) \sim \theta_l(z_f))]\Delta z_{g,w}$$

$$i = 1$$

The adjusting volume WADJ is calculated in loop 200, and the time to ponding TIMPND in loop 250. If TIMPND is greater than the amount of time remaining in the current time step TRMDR, then unsaturated infiltration is deemed to be occurring over the entire time step. In this case, the amount of water infiltrating over the time step is assigned to the first level of the water movement matrix WMOVE and to the accounting variable WADD, and the temperature of the infiltrating water is assigned to the first level of the matrix TMOVE.

In loop 300 WADD is partitioned over the soil profile by comparing in turn the liquid water content of each soil layer with the calculated liquid water content behind the wetting front THLINF, and decrementing WADD layer by layer until a layer is reached in which the remainder of WADD is insufficient to raise the liquid water content to THLINF. If this condition is reached, LZF is set to the index of the soil layer; the depth of the wetting front DZF within the layer, obtained as $WADD/(THLINF-THLIQX)$, is added to the depth of the bottom of the overlying layer to obtain ZF.

In loop 400, the water content in each soil layer J existing above ZF is assigned to the J+1 level of the water movement matrix WMOVE, and the respective water temperatures are assigned to TMOVE.

If $TIMPND < TRMDR$, the amount of water infiltrating between the start of the time step and TIMPND is again assigned to the first level of the water movement matrix WMOVE, and the temperature of the infiltrating water is assigned to the first level of the matrix TMOVE. The depth DZF of the wetting front within the layer containing it is calculated by subtracting the depth of the bottom of the overlying layer from ZF.

In loop 500, the water content in each soil layer J existing above ZF is assigned to the J+1 level of the water movement matrix WMOVE, and the respective water temperatures are assigned to TMOVE.

Finally, the time remaining in the current time step after the period of unsaturated infiltration is recalculated, and the counter NINF is set to LZF+1.

Parameters

<i>wmove</i>	Water movement matrix [m^3m^{-2}]
<i>tmove</i>	Temperature matrix associated with ground water movement [C]
<i>lzf</i>	Index of soil layer in which wetting front is located
<i>ninf</i>	Number of levels involved in water movement
<i>trmdr</i>	Time remaining in current time step [s]
<i>tpond</i>	Temperature of ponded water [C]
<i>zpond</i>	Depth of ponded water [m](z_p)
<i>r</i>	Rainfall rate at ground surface [ms^{-1}]
<i>tr</i>	Temperature of rainfall [C]
<i>evap</i>	Surface evaporation rate [ms^{-1}]
<i>psif</i>	Soil water suction across the wetting front [m](Ψ_f)
<i>grkinf</i>	Hydraulic conductivity of soil behind the wetting front [ms^{-1}](K)
<i>thlinf</i>	Volumetric liquid water content behind the wetting front [m^3m^{-3}]
<i>thliqx</i>	Volumetric liquid water content of soil layer [m^3m^{-3}]
<i>tbarwx</i>	Temperature of water in soil layer [C]
<i>delzx</i>	Permeable depth of soil layer [m]($\Delta z_{z,w}$)
<i>zbotx</i>	Depth of bottom of soil layer [m]
<i>fmax</i>	Maximum infiltration rate, defined as minimum value of GRKINF
<i>zf</i>	Depth of the wetting front [m](z_f)
<i>igrn</i>	Flag to indicate whether infiltration is occurring

General calculations performed: The infiltration rate F_{inf} under saturated conditions is calculated as

$$F_{inf} = K_{inf}[(\Psi_f + z_f + z_p)/z_f]$$

where K_{inf} is the hydraulic conductivity of the soil behind the wetting front, Ψ_f is the soil moisture suction across the wetting front, z_f is the depth of the wetting front, and z_p is the depth of water ponded on the surface. Since Ψ_f will vary by soil layer, and z_f and z_p will vary with time, the period of infiltration is divided into two-minute segments. A maximum iteration flag NEND is defined as the number of iteration segments plus 100, as a safeguard against runaway iterations. Since the surface infiltration rate will be limited by the lowest infiltration rate encountered, a maximum infiltration rate FMAX is defined as the minimum value of GRKINF, the hydraulic conductivity behind the wetting front, in all of the soil layers above and including that containing the wetting front.

In loop 200, a check is performed to determine whether the liquid water content of the current soil layer, THLIQX, equals or exceeds that behind the wetting front, THLINF. If so, the depth of the wetting front is reset to the depth

of the soil layer. The water content of the soil layer is assigned to the level of the water movement matrix WMOVE corresponding to the soil layer index plus 1, and the temperature of the water in the layer is assigned to the same level of the matrix TMOVE. FMAX is recalculated, and the flags LZF and NINF are each incremented by 1. The flag ISIMP is set to 1, indicating that the following calculations are to be bypassed for this iteration.

If ISIMP is not 1, the time period DTFLOW applying to the current iteration loop is set to two minutes or to the remainder of the time step, whichever is less. If GRKINF for the current soil layer is not vanishingly small, the flag ISIMP is set to -2. Otherwise, it is deemed that infiltration is suppressed, and the temperature and depth of water ponded on the surface are simply updated. The temperature of the ponded water is calculated as the weighted average of the current pond temperature and the rainfall added to it. The ponded water remaining after rainfall and evaporation have taken place is calculated as ZPTEST. If ZPTEST is less than zero, it is deduced that evaporation must have removed the ponded water before the end of the current iteration loop. If this is the case, the time period of the current iteration loop is recalculated as the amount of time required for the difference between the evaporation and the rainfall rates to consume the ponded water, and the pond depth ZPOND is set to zero. Otherwise, ZPOND is set to ZPTEST. Finally, ISIMP is set to -1.

The 400 loop addresses the infiltration process under saturated conditions. Such infiltration is modelled as “piston flow”. First the current infiltration rate FINF is calculated using the equation given above. If the wetting front has passed the bottom of the lowest soil layer, PSIF is neglected. If FINF is greater than the rainfall rate R, FINF is set equal to R; if FINF is greater than CFMAX, FINF is set equal to FMAX. If the wetting front has not passed the bottom of the lowest soil layer, the change in depth of the wetting front DZF over the current time interval is calculated from the amount of infiltrating water WINF and the volumetric water content behind the wetting front, THLINF. The amount of soil water WDISP displaced by this movement of the wetting front is calculated from DZF and THLIQX, and the depth to which this water penetrates, DZDISP, is calculated as $WDISP / (THLINF - THLIQX)$. The amount of soil water WABS entrained by the movement of WDISP itself is calculated as the product of DZDISP and THLIQX. The change in depth of the wetting front, behind which the liquid water content of the soil layer is THLINF, is now the sum of the depth represented by infiltration of water at the surface, DZF, and the depth represented by displacement of the pre-existing soil water, DZDISP. If this change in depth causes the wetting front to move beyond the bottom of the current soil layer, DTFLOW is recalculated as the amount of time required for the composite wetting front to reach the bottom of the soil layer, and DZF, WDISP, DZDISP and WABS are likewise recalculated. As in the case for ISIMP = -1, the temperature of the ponded water on the surface is calculated as the weighted average of the current pond temperature and the rainfall added to it. The ponded water remaining after rainfall, infiltration and evaporation have taken place is calculated as ZPTEST. If ZPTEST is less than zero, it is deduced that infiltration and evaporation must have removed the ponded water before the end of the current iteration loop. If this is the case, the time period of the current iteration loop is recalculated as the amount of time required for the infiltration and evaporation minus the rainfall to consume the ponded water. The pond depth ZPOND is set to zero; if the wetting front has not passed the bottom of the lowest soil layer, DZF, WDISP, DZDISP and WABS are recalculated. Otherwise, ZPOND is set to ZPTEST. Finally, the first layer of the water movement matrix WMOVE is incremented with the amount of the infiltrated water, and the first layer of the matrix TMOVE with the temperature of the infiltrated water. The last layer of WMOVE is incremented by WDISP+WABS, and the depth of the wetting front by DZF+DZDISP.

In the 500 loop, if $ISIMP < 0$ (i.e. water movement has occurred), the time remaining in the current time step is recalculated. If the wetting front is at a soil layer boundary, if the time remaining is non-zero, if the wetting front is still within the modelled soil column, and if the calculated water content behind the wetting front is greater than zero, FMAX is updated, and LZF and NINF are incremented by 1. The NINF level of the TMOVE matrix is set to the water temperature of the new soil layer.

At the end of the iteration pass, checks are done in the 600 loop to ascertain whether the number of iteration passes is still less than NEND, whether either ponded water still exists or rain is still falling, and whether there is still time remaining in the current time step. If these conditions are all fulfilled, the counter NPNTS representing the number of points in the current vector of mosaic tiles for which infiltration is still occurring is incremented by 1. Otherwise, the iteration flag for the current tile is changed from 1 to 0, signaling the end of the saturated infiltration calculations for that tile.

<i>delzz</i>	Soil layer depth variable used in TWCALC/TMCALC [m]
<i>delzw</i>	Permeable thickness of soil layer [m]
<i>delz</i>	Overall thickness of soil layer [m]
<i>isand</i>	Sand content flag

In the first three loops, various subarea arrays and internal CLASSW variables are initialized.

At the end of the 100 loop, a preliminary calculation of the precipitation diagnostics over the four subareas is carried out, as follows:

The rainfall incident on the vegetation, PCLC, is summed over the vegetated subareas FC and FCS, minus the fraction that falls through the gaps in the canopy (denoted by the sky view factors FSVF and FSVFS respectively). The rainfall incident on the snowpack PCPN is the sum of the rainfall on the snow-covered bare area FGS, and that on the snow under the gaps in the canopy in subarea FCS. The rainfall incident on bare ground, PCPG, is the sum of the rainfall on the snow-free bare area FG, and that on the ground under the gaps in the canopy in subarea FC. The snowfall incident on the vegetation, PCFC, as in the case of rainfall, is summed over the vegetation subareas FC and FCS, minus the fraction that falls through the gaps in the canopy. The remaining amount is assigned to snowfall incident on the snow pack, PCPN.

In loops 200 to 550, each of the four subareas is addressed in turn. Additional variables are initialized, and an empirical correction is applied to the saturated hydraulic conductivity in each of the soil layers over the subarea, to account for the viscosity of water at the layer temperature (Dingman, 2002) [Lawrence_Dingman2002-sq] :

$$K'_{sat} = (1.7915 * 10^{-3})K_{sat} / [(2.0319 * 10^{-4}) + (1.5883 * 10^{-3})exp(-T_g^{0.9}/22.0)]$$

Next, a preliminary calculation of the water vapour flux diagnostics for each subarea is carried out. Over the vegetated subareas, first the canopy evaporative flux is assigned to sublimation if there is snow present on the canopy (since it is assumed that any water present exists within or underneath the snow). Then, if the sublimation rate is upward, it is assigned to the diagnostic variable QFCF; if it is downward, the portion of the flux corresponding to the canopy-covered area is assigned to QFCF and that corresponding to the gap area to QFN. Similarly, if the evaporation rate is upward it is assigned to the diagnostic variable QFCL; if it is downward, the flux corresponding to the canopy-covered area is assigned to QFCL and that corresponding to the gap area to QFN over subarea FCS and to QFG over subarea FC. Over the non-vegetated subareas, the evaporation rates are assigned to QFN for subarea GS, and to QFG for subarea G.

For the purposes of the subsequent water balance calculations done in the other CLASSW subroutines, the subarea snowfall is lumped together with any simultaneously occurring sublimation, and the subarea rainfall with any simultaneously occurring evaporation. Depending on whether the sum of the snowfall and the sublimation, and the sum of the rainfall and the evaporation, are positive (downward) or negative (upward), corrections are applied to the appropriate diagnostic variables, and the snowfall/rainfall are set to the net flux if downward and the sublimation/evaporation are set to the net flux if upward. The smaller of the two fluxes in the sums are set to zero.

Finally, ponded water and snow pack physical characteristics are set, including the snow heat capacity, which is calculated from the heat capacities of ice and water C_i and C_w , the snow, ice and water densities ρ_s , ρ_i , and ρ_w , and the water content and depth of the snow pack w_s and z_s , as follows:

$$C_s = C_i[\rho_s/\rho_i] + C_w w_s/[\rho_w z_s]$$

6.79 src/XIT.f File Reference

Purpose: Print the name of the subroutine and an error code when an error condition is encountered.

Functions/Subroutines

- subroutine [xit](#) (NAME, N)

6.79.1 Detailed Description

Purpose: Print the name of the subroutine and an error code when an error condition is encountered.

6.79.2 Function/Subroutine Documentation

6.79.2.1 subroutine `xit` (`character*(*) NAME`, `N`)

Parameters

<i>name</i>	Name of the subroutine in which the error was found N: error code
-------------	---

In CLASS, this subroutine is called when a test of ambient values of selected variables is performed and an abnormal condition is encountered. The name of the subroutine in which the condition arose is passed in, and is printed together with an error code, flagging the location of the error in the subroutine. A call to abort is then executed.
